

Package ‘emmeans’

March 5, 2026

Type Package

Title Estimated Marginal Means, aka Least-Squares Means

Version 2.0.2

Date 2026-02-20

Maintainer Julia Piaskowski <julia.piask@gmail.com>

Depends R (>= 4.1.0)

Imports estimability (>= 1.4.1), graphics, methods, mvtnorm, numDeriv,
rlang, stats, utils

Suggests bayesplot, bayestestR, biglm, brms, car, coda (>= 0.17),
compositions, ggplot2, knitr, lattice, lme4, lmerTest (>=
2.0.32), logspline, MASS, mediation, mgcv, multcomp,
multcompView, MuMIn, nlme, ordinal (>= 2014.11-12), pbkrtest
(>= 0.4-1), rmarkdown, robmixglm, rsm, sandwich, scales,
splines, testthat, tibble, xtable (>= 1.8-2)

Enhances CARBayes, coxme, gee, geopack, MCMCglmm, MCMCpack, mice,
nnet, pscl, rstanarm, sommer, survival

BugReports <https://github.com/rvlenth/emmeans/issues>

LazyData yes

ByteCompile yes

Description Obtain estimated marginal means (EMMs) for many linear, generalized linear, and mixed models. Compute contrasts or linear functions of EMMs, trends, and comparisons of slopes. Plots and other displays. Least-squares means are discussed, and the term “estimated marginal means” is suggested, in Searle, Speed, and Milliken (1980) Population marginal means in the linear model: An alternative to least squares means, *The American Statistician* 34(4), 216-221 <[doi:10.1080/00031305.1980.10483031](https://doi.org/10.1080/00031305.1980.10483031)>.

emmeans-package

*Estimated marginal means (aka Least-squares means)***Description**

This package provides methods for obtaining estimated marginal means (EMMs, also known as least-squares means) for factor combinations in a variety of models. Supported models include [generalized linear] models, models for counts, multivariate, multinomial and ordinal responses, survival models, GEEs, and Bayesian models. For the latter, posterior samples of EMMs are provided. The package can compute contrasts or linear combinations of these marginal means with various multiplicity adjustments. One can also estimate and contrast slopes of trend lines. Some graphical displays of these results are provided.

Overview

Vignettes A number of vignettes are provided to help the user get acquainted with the **emmeans** package and see some examples.

Concept Estimated marginal means (see Searle *et al.* 1980) are popular for summarizing linear models that include factors. For balanced experimental designs, they are just the marginal means. For unbalanced data, they in essence estimate the marginal means you *would* have observed that the data arisen from a balanced experiment. Earlier developments regarding these techniques were developed in a least-squares context and are sometimes referred to as “least-squares means”. Since its early development, the concept has expanded far beyond least-squares settings.

Reference grids The implementation in **emmeans** relies on our own concept of a *reference grid*, which is an array of factor and predictor levels. Predictions are made on this grid, and estimated marginal means (or EMMs) are defined as averages of these predictions over zero or more dimensions of the grid. The function `ref_grid` explicitly creates a reference grid that can subsequently be used to obtain least-squares means. The object returned by `ref_grid` is of class "emmGrid", the same class as is used for estimated marginal means (see below).

Our reference-grid framework expands slightly upon Searle *et al.*'s definitions of EMMs, in that it is possible to include multiple levels of covariates in the grid.

Models supported As is mentioned in the package description, many types of models are supported by the package. See `vignette("models", "emmeans")` for full details. Some models may require other packages be installed in order to access all of the available features. For models not explicitly supported, it may still be possible to do basic post hoc analyses of them via the `qdr` function.

Estimated marginal means The `emmeans` function computes EMMs given a fitted model (or a previously constructed `emmGrid` object), using a specification indicating what factors to include. The `emtrends` function creates the same sort of results for estimating and comparing slopes of fitted lines. Both return an `emmGrid` object.

Summaries and analysis The `summary.emmGrid` method may be used to display an `emmGrid` object. Special-purpose summaries are available via `confint.emmGrid` and `test.emmGrid`, the latter of which can also do a joint test of several estimates. The user may specify by variables, multiplicity-adjustment methods, confidence levels, etc., and if a transformation or link function is involved, may reverse-transform the results to the response scale.

Contrasts and comparisons The `contrast` method for `emmGrid` objects is used to obtain contrasts among the estimates; several standard contrast families are available such as deviations from the mean, polynomial contrasts, and comparisons with one or more controls. Another `emmGrid` object is returned, which can be summarized or further analyzed. For convenience, a `pairs.emmGrid` method is provided for the case of pairwise comparisons.

Graphs The `plot.emmGrid` method will display side-by-side confidence intervals for the estimates, and/or "comparison arrows" whereby the *P* values of pairwise differences can be observed by how much the arrows overlap. The `emmip` function displays estimates like an interaction plot, multi-paneled if there are by variables. These graphics capabilities require the `lattice` package be installed.

MCMC support When a model is fitted using MCMC methods, the posterior chains(s) of parameter estimates are retained and converted into posterior samples of EMMs or contrasts thereof. These may then be summarized or plotted like any other MCMC results, using tools in, say `coda` or `bayesplot`.

multcomp interface The `as.glht` function and `glht` method for `emmGrid`s provide an interface to the `glht` function in the **multcomp** package, thus providing for more exacting simultaneous estimation or testing. The package also provides an `emm` function that works as an alternative to `mcp` in a call to `glht`.

Description

These are useful utility functions for creating a compact version of an `emmGrid` object that may be saved and later reconstructed, or for converting old `ref.grid` or `lsmobj` objects into `emmGrid` objects.

Usage

```
## S3 method for class 'emmGrid'
as.list(x, model.info.slot = FALSE, ...)

as.emm_list(object, ...)

as.emmGrid(object, ...)
```

Arguments

<code>x</code>	An <code>emmGrid</code> object
<code>model.info.slot</code>	Logical value: Include the <code>model.info</code> slot? Set this to <code>TRUE</code> if you want to preserve the original call and information needed by the <code>submodel</code> option. If <code>FALSE</code> , only the nesting information (if any) is saved
<code>...</code>	In <code>as.emmGrid</code> , additional arguments passed to <code>update.emmGrid</code> before returning the object. This argument is ignored in <code>as.list.emmGrid</code>
<code>object</code>	Object to be converted to class <code>emmGrid</code> . It may be a <code>list</code> returned by <code>as.list.emmGrid</code> , or a <code>ref.grid</code> or <code>lsmobj</code> object created by emmeans 's predecessor, the lsmeans package. An error is thrown if <code>object</code> cannot be converted.

Details

An `emmGrid` object is an S4 object, and as such cannot be saved in a text format or saved without a lot of overhead. By using `as.list`, the essential parts of the object are converted to a list format that can be easily and compactly saved for use, say, in another session or by another user. Providing this list as the arguments for `emmobj` allows the user to restore a working `emmGrid` object.

Value

`as.list.emmGrid` returns an object of class `list`.

`as.emm_list` returns an object of class `emm_list`.

`as.emmGrid` returns an object of class `emmGrid`. However, in fact, both `as.emmGrid` and `as.emm_list` check for an attribute in `object` to decide whether to return an `emmGrid` or `emm_list` object.

See Also

[emmobj](#)

Examples

```
pigs.lm <- lm(log(conc) ~ source + factor(percent), data = pigs)
pigs.sav <- as.list(ref_grid(pigs.lm))

pigs.anew <- as.emmGrid(pigs.sav)
emmeans(pigs.anew, "source")
```

as.mcmc.emmGrid *Support for MCMC-based estimation*

Description

When a model is fitted using Markov chain Monte Carlo (MCMC) methods, its reference grid contains a `post.beta` slot. These functions transform those posterior samples to posterior samples of EMMs or related contrasts. They can then be summarized or plotted using, e.g., functions in the `coda` package.

Usage

```
## S3 method for class 'emmGrid'
as.mcmc(x, names = TRUE, sep.chains = TRUE, likelihood,
        NE.include = FALSE, ...)

## S3 method for class 'emm_list'
as.mcmc(x, which = 1, ...)

## S3 method for class 'emmGrid'
as.mcmc.list(x, names = TRUE, ...)

## S3 method for class 'emm_list'
as.mcmc.list(x, which = 1, ...)
```

Arguments

<code>x</code>	An object of class <code>emmGrid</code>
<code>names</code>	Logical scalar or vector specifying whether variable names are appended to levels in the column labels for the <code>as.mcmc</code> or <code>as.mcmc.list</code> result – e.g., column names of <code>treat A</code> and <code>treat B</code> versus just <code>A</code> and <code>B</code> . When there is more than one variable involved, the elements of <code>names</code> are used cyclically.
<code>sep.chains</code>	Logical value. If <code>TRUE</code> , and there is more than one MCMC chain available, an <code>mcmc.list</code> object is returned by <code>as.mcmc</code> , with separate EMMs posteriors in each chain.
<code>likelihood</code>	Character value or function. If given, simulations are made from the corresponding posterior predictive distribution. If not given, we obtain the posterior distribution of the parameters in object. See Prediction section below.

NE.include	Logical value. If TRUE, non-estimable columns are kept but returned as columns of NA values (this may create errors or warnings in subsequent analyses using, say, coda). If FALSE, non-estimable columns are dropped, and a warning is issued. (If all are non-estimable, an error is thrown.)
...	arguments passed to other methods
which	item in the emm_list to use

Value

An object of class `mcmc` or `mcmc.list`.

Details

When the object's `post.beta` slot is non-trivial, `as.mcmc` will return an `mcmc` or `mcmc.list` object that can be summarized or plotted using methods in the **coda** package. In these functions, `post.beta` is transformed by post-multiplying it by `t(linfct)`, creating a sample from the posterior distribution of LS means. In `as.mcmc`, if `sep.chains` is TRUE and there is in fact more than one chain, an `mcmc.list` is returned with each chain's results. The `as.mcmc.list` method is guaranteed to return an `mcmc.list`, even if it comprises just one chain.

Prediction

When `likelihood` is specified, it is used to simulate values from the posterior predictive distribution corresponding to the given likelihood and the posterior distribution of parameter values. Denote the likelihood function as $f(y|\theta, \phi)$, where y is a response, θ is the parameter estimated in object, and ϕ comprises zero or more additional parameters to be specified. If `likelihood` is a function, that function should take as its first argument a vector of θ values (each corresponding to one row of `object@grid`). Any ϕ values should be specified as additional named function arguments, and passed to `likelihood` via `...`. This function should simulate values of y .

A few standard likelihoods are available by specifying `likelihood` as a character value. They are:

"normal" The normal distribution with mean θ and standard deviation specified by additional argument `sigma`

"binomial" The binomial distribution with success probability θ , and number of trials specified by `trials`

"poisson" The Poisson distribution with mean θ (no additional parameters)

"gamma" The gamma distribution with scale parameter θ and shape parameter specified by `shape`

Examples

```
if(requireNamespace("coda"))
  emm_example("as.mcmc-coda")
  # Use emm_example("as.mcmc-coda", list = TRUE) # to see just the code
```

`auto.noise`*Auto Pollution Filter Noise*

Description

Three-factor experiment comparing pollution-filter noise for two filters, three sizes of cars, and two sides of the car.

Usage`auto.noise`**Format**

A data frame with 36 observations on the following 4 variables.

`noise` Noise level in decibels (but see note) - a numeric vector.

`size` The size of the vehicle - an ordered factor with levels S, M, L.

`type` Type of anti-pollution filter - a factor with levels `Std` and `Octel`

`side` The side of the car where measurement was taken – a factor with levels L and R.

Details

The data are from a statement by Texaco, Inc., to the Air and Water Pollution Subcommittee of the Senate Public Works Committee on June 26, 1973. Mr. John McKinley, President of Texaco, cited an automobile filter developed by Associated Octel Company as effective in reducing pollution. However, questions had been raised about the effects of filters on vehicle performance, fuel consumption, exhaust gas back pressure, and silencing. On the last question, he referred to the data included here as evidence that the silencing properties of the Octel filter were at least equal to those of standard silencers.

Note

While the data source claims that noise is measured in decibels, the values are implausible. I believe that these measurements are actually in tenths of dB (centibels?). Looking at the values in the dataset, note that every measurement ends in 0 or 5, and it is reasonable to believe that measurements are accurate to the nearest half of a decibel.

Source

The dataset was obtained from the Data and Story Library (DASL) at Carnegie-Mellon University. Apparently it has since been removed. The original dataset was altered by assigning meaningful names to the factors and sorting the observations in random order as if this were the run order of the experiment.

Examples

```
# (Based on belief that noise/10 is in decibel units)
noise.lm <- lm(noise/10 ~ size * type * side, data = auto.noise)

# Interaction plot of predictions
emmip(noise.lm, type ~ size | side)

# Confidence intervals
plot(emmeans(noise.lm, ~ size | side*type))
```

cld.emmGrid

Compact letter displays

Description

A method for `multcomp::cld()` is provided for users desiring to produce compact-letter displays (CLDs). This method uses the Piepho (2004) algorithm (as implemented in the **multcompView** package) to generate a compact letter display of all pairwise comparisons of estimated marginal means. The function obtains (possibly adjusted) P values for all pairwise comparisons of means, using the `contrast` function with `method = "pairwise"`. When a P value exceeds alpha, then the two means have at least one letter in common.

Usage

```
## S3 method for class 'emmGrid'
cld(object, details = FALSE, sort = TRUE, by,
     alpha = 0.05, Letters = c("1234567890", LETTERS, letters),
     reversed = decreasing, decreasing = FALSE, signif.sets = FALSE,
     delta = 0, ...)

## S3 method for class 'emm_list'
cld(object, ..., which = 1)
```

Arguments

<code>object</code>	An object of class <code>emmGrid</code>
<code>details</code>	Logical value determining whether detailed information on tests of pairwise comparisons is displayed
<code>sort</code>	Logical value determining whether the EMMs are sorted before the comparisons are produced. When <code>TRUE</code> , the results are displayed according to <code>reversed</code> .
<code>by</code>	Character value giving the name or names of variables by which separate families of comparisons are tested. If <code>NULL</code> , all means are compared. If missing, the object's <code>by.vars</code> setting, if any, is used.
<code>alpha</code>	Numeric value giving the significance level for the comparisons

Letters	Character vector of letters to use in the display. Any strings of length greater than 1 are expanded into individual characters
reversed, decreasing	Logical value (passed to <code>multcompView::multcompLetters</code> .) If TRUE, the order of use of the letters is reversed. Either <code>reversed</code> or <code>decreasing</code> may be specified, thus providing compatibility with both <code>multcompView::multcompLetters(..., reversed, ...)</code> and <code>multcomp::cld(..., decreasing, ...)</code> . In addition, if both <code>sort</code> and <code>reversed</code> are TRUE, the sort order of results is reversed.
<code>signif.sets</code>	Logical value. If FALSE (and <code>delta = 0</code>), a ‘traditional’ compact-letter display is constructed with groupings representing sets of estimates that are not statistically different. If TRUE, the criteria are reversed so that two estimates sharing the same symbol test as significantly different. See also <code>delta</code> .
<code>delta</code>	Numeric value passed to <code>test.emmGrid</code> . If this is positive, it is used as an equivalence threshold in the TOST procedure for two-sided equivalence testing. In the resulting compact letter display, two estimates share the same grouping letter only if they are found to be statistically equivalent – that is, groupings reflect actual <i>findings</i> of equivalence rather than failure to find a significant difference. When <code>delta</code> is nonzero, <code>signif.sets</code> is ignored.
...	Arguments passed to <code>contrast</code> (for example, an adjust method)
<code>which</code>	Which element of the <code>emm_list</code> object to process (If length exceeds one, only the first one is used)

Value

A `summary_emm` object showing the estimated marginal means plus an additional column labeled `.group` (when `signif.sets = FALSE`), `.signif.set` (when `signif.sets = TRUE`), or `.equiv.set` (when `delta > 0`).

Note

We warn that the default display encourages a poor practice in interpreting significance tests. Such CLDs are misleading because they visually group means with comparisons $P > \alpha$ as though they are equal, when in fact we have only failed to prove that they differ. A better alternative if one wants to show groupings is to specify an equivalence threshold `delta`; then groupings will be based on actual findings of equivalence. Another way to display actual findings is to set `signif.sets = TRUE`, so that estimates in the same group are those found to be statistically *different*. Obviously, these different options require different interpretations of the results; the annotations and the label given the final column help guide how to assess the results.

As further alternatives, consider `pwpp` (graphical display of P values) or `pwpm` (matrix display).

References

Piepho, Hans-Peter (2004) An algorithm for a letter-based representation of all pairwise comparisons, *Journal of Computational and Graphical Statistics*, 13(2), 456-466.

Examples

```
if(requireNamespace("multcomp"))
  emm_example("cld-multcomp")
  # Use emm_example("cld-multcomp", list = TRUE) # to just list the code
```

 comb_fac

Manipulate factors in a reference grid

Description

These functions manipulate the levels of factors comprising a reference grid by combining factor levels, splitting a factor's levels into combinations of newly-defined factors, creating a grouping factor in which factor(s) levels are nested, or permuting the order of levels of a factor

Usage

```
comb_fac(object, facs, newname = paste(facs, collapse = "."),
  drop = FALSE, ...)

split_fac(object, fac, newfacs, ...)

add_grouping(object, newname, refname, newlevs, ...)

add_submodels(object, ..., newname = "model")

permute_levels(object, fac, pos)
```

Arguments

object	An object of class <code>emmGrid</code>
facs	Character vector. The names of the factors to combine
newname	Character name of grouping factor to add (different from any existing factor in the grid)
drop	Logical value. If <code>TRUE</code> , any levels of the new factor that are dropped if all occurrences in the newly reconstructed object have weight zero. If <code>FALSE</code> , all levels are retained. (This argument is ignored if there is no <code>.wgt.</code> column in <code>object@grid</code> .)
...	arguments passed to other methods
fac	The name of a factor that is part of the grid in object
newfacs	A named list with the names of new factors and their levels. The names must not already exist in the object, and the product of the lengths of the levels must equal the number of levels of <code>fac</code> .
refname	Character name(s) of the reference factor(s)

newlevs	Character vector or factor of the same length as that of the (combined) levels for refname. The grouping factor newname will have the unique values of newlevs as its levels. The order of levels in newlevs is the same as the order of the level combinations produced by <code>expand.grid</code> applied to the levels of refname – that is, the first factor’s levels change the fastest and the last one’s vary the slowest.
pos	Integer vector consisting of some permutation of the sequence $1:k$, where k is the number of levels of fac. This determines which position each level of fac will occupy after the levels are permuted; thus, if the levels of fac are A, B, C, D, and <code>pos = c(3, 1, 2, 4)</code> , then the permuted levels will be B, C, A, D.

Value

A modified object of class `emmGrid`

The `comb_fac` function

`comb_fac` combines the levels of factors into a single factor in the reference grid (similar to `interaction`). This new factor replaces the factors that comprise it.

Additional note: The choice of whether to drop levels or not can make a profound difference. If the goal is to combine factors for use in `joint_tests`, we advise *against* `drop = TRUE` because that might change the weights used in deriving marginal means. If combining factors in a nested structure, dropping unused cases can considerably reduce the storage required.

The `split_fac` function

The levels in `newfacs` are expanded via `expand.grid` into combinations of levels, and the factor `fac` is replaced by those factor combinations. Unlike `add_grouping`, this creates a crossed, rather than a nested structure. Note that the order of factor combinations is systematic with the levels of first factor in `newfacs` varying the fastest; and those factor combinations are assigned respectively to the levels of `fac` as displayed in `str(object)`.

The `add_grouping` function

This function adds a grouping factor to an existing reference grid or other `emmGrid` object, such that the levels of one or more existing factors (call them the reference factors) are mapped to a smaller number of levels of the new grouping factor. The reference factors are then nested in a new grouping factor named `newname`, and a new nesting structure `refname %in% newname`. This facilitates obtaining marginal means of the grouping factor, and contrasts thereof.

Additional notes: By default, the levels of `newname` will be ordered alphabetically. To dictate a different ordering of levels, supply `newlevs` as a factor having its levels in the desired order.

When `refname` specifies more than one factor, this can fundamentally (and permanently) change what is meant by the levels of those individual factors. For instance, in the `gwrg` example below, there are two levels of `wool` nested in each `prod`; and that implies that we now regard these as four different kinds of wool. Similarly, there are five different tensions (L, M, H in `prod 1`, and L, M in `prod 2`).

The add_submodels function

This function updates object with a named list of submodels specified in These are rbinded together and the corresponding rows for each submodel are assigned a factor named newname with levels equal to the names in This facilitates comparing estimates obtained from different submodels. For this to work, the underlying model object must be of a class supported by the submodel argument of `update.emmGrid`.

The permute_levels function

This function permutes the levels of fac. The returned object has the same factors, same by variables, but with the levels of fac permuted. The order of the columns in `object@grid` may be altered.

NOTE: fac must not be nested in another factor. `permute_levels` throws an error when fac is nested.

NOTE: Permuting the levels of a numeric predictor is tricky. For example, if you want to display the new ordering of levels in `emmip()`, you must add the arguments `style = "factor"` and `nesting.order = TRUE`.

Examples

```
mtcars.lm <- lm(mpg ~ factor(vs)+factor(cyl)*factor(gear), data = mtcars)
(v.c.g <- ref_grid(mtcars.lm))
(v.cg <- comb_fac(v.c.g, c("cyl", "gear")))
```

One use is obtaining a single test for the joint contributions of two factors:

```
joint_tests(v.c.g)

joint_tests(v.cg)
```

undo the 'comb_fac' operation:

```
split_fac(v.cg, "cyl.gear", list(cyl = c(4, 6, 8), gear = 3:5))
```

```
IS.glm <- glm(count ~ spray, data = InsectSprays, family = poisson)
IS.emm <- emmeans(IS.glm, "spray")
IS.new <- split_fac(IS.emm, "spray", list(A = 1:2, B = c("low", "med", "hi")))
str(IS.new)
```

```
fiber.lm <- lm(strength ~ diameter + machine, data = fiber)
(frg <- ref_grid(fiber.lm) )
```

Suppose the machines are two different brands

```
brands <- factor(c("FiberPro", "FiberPro", "Acme"), levels = c("FiberPro", "Acme"))
(gfrg <- add_grouping(frg, "brand", "machine", brands) )
```

```
emmeans(gfrg, "machine")

emmeans(gfrg, "brand")
```

More than one reference factor

```
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
```

```

gwrgr <- add_grouping(ref_grid(warp.lm),
  "prod", c("tension", "wool"), c(2, 1, 1, 1, 2, 1))
  # level combinations:      LA MA HA  LB MB HB

emmeans(gwrgr, ~ wool * tension) # some NAs due to impossible combinations

emmeans(gwrgr, "prod")

## Using 'add_submodels' to compare adjusted and unadjusted means
fibint.lm <- lm(strength ~ machine * diameter, data = fiber)
fibsub <- add_submodels(emmeans(fibint.lm, "machine"),
  full = ~ ., additive = ~ . - machine:diameter, unadj = ~ machine)
emmeans(fibsub, pairwise ~ model | machine, adjust = "none")

# Permuting factor levels...
str(v.c.g)
str(permute_levels(v.c.g, "cyl", c(2,3,1)))

```

 contrast

Contrasts and linear functions of EMMs

Description

These methods provide for follow-up analyses of `emmGrid` objects: Contrasts, pairwise comparisons, tests, and confidence intervals. They may also be used to compute arbitrary linear functions of predictions or EMMs.

Usage

```

contrast(object, ...)

## S3 method for class 'emmGrid'
contrast(object, method = "eff", interaction = FALSE, by,
  offset = NULL, scale = NULL, name = "contrast",
  options = get_emm_option("contrast"), type, adjust, simple,
  combine = FALSE, ratios = TRUE, parens, enhance.levels = TRUE, wts,
  ...)

## S3 method for class 'emmGrid'
pairs(x, reverse = FALSE, ...)

## S3 method for class 'emmGrid'
coef(object, ...)

## S3 method for class 'emmGrid'
weights(object, ...)

```

Arguments

object	An object of class <code>emmGrid</code>
...	Additional arguments passed to other methods
method	Character value giving the root name of a contrast method (e.g. "pairwise" – see emmc-functions). Alternatively, a function of the same form, or a named list of coefficients (for a contrast or linear function) that must each conform to the number of results in each by group. In a multi-factor situation, the factor levels are combined and treated like a single factor.
interaction	Character vector, logical value, or list. If this is specified, method is ignored. See the "Interaction contrasts" section below for details.
by	Character names of variable(s) to be used for "by" groups. The contrasts or joint tests will be evaluated separately for each combination of these variables. If object was created with by groups, those are used unless overridden. Use <code>= NULL</code> to use no by groups at all.
offset, scale	Numeric vectors of the same length as each by group. The scale values, if supplied, multiply their respective linear estimates, and any offset values are added. Scalar values are also allowed. (These arguments are ignored when interaction is specified.)
name	Character name to use to override the default label for contrasts used in table headings or subsequent contrasts of the returned object.
options	If non-NULL, a named list of arguments to pass to <code>update.emmGrid</code> , just after the object is constructed.
type	Character: prediction type (e.g., "response") – added to options
adjust	Character: adjustment method (e.g., "bonferroni") – added to options
simple	Character vector or list: Specify the factor(s) <i>not</i> in by, or a list thereof. See the section below on simple contrasts.
combine	Logical value that determines what is returned when simple is a list. See the section on simple contrasts.
ratios	Logical value determining how log and logit transforms are handled. These transformations are exceptional cases in that there is a valid way to back-transform contrasts: differences of logs are logs of ratios, and differences of logits are odds ratios. If <code>ratios = TRUE</code> and summarized with <code>type = "response"</code> , contrast results are back-transformed to ratios whenever we have true contrasts (coefficients sum to zero). For other transformations, there is no natural way to back-transform contrasts, so even when summarized with <code>type = "response"</code> , contrasts are computed and displayed on the linear-predictor scale. Similarly, if <code>ratios = FALSE</code> , log and logit transforms are treated in the same way as any other transformation.
parens	character or NULL. If a character value, the labels for levels being contrasted are parenthesized if they match the regular expression in <code>parens[1]</code> (via grep). The default is <code>emm_option("parens")</code> . Optionally, <code>parens</code> may contain second and third elements specifying what to use for left and right parentheses (default "(" and ")"). Specify <code>parens = NULL</code> or <code>parens = "a^"</code> (which won't match anything) to disable all parenthesization.

<code>enhance.levels</code>	character or logical. If character, the levels of the named factors that are contrasted are enhanced by appending the name of the factor; e.g., if a factor named "trt" has levels A and B, a trt comparison is labeled trtA - trtB. If <code>enhance.levels</code> is logical, then if TRUE (the default), only factors with numeric levels are enhanced; and of course if FALSE, no levels are enhanced. The levels of by variables are not enhanced, and any names of factors that don't exist are silently ignored. To enhance the labels beyond what is done here, change them directly via <code>levels<-</code> .
<code>wts</code>	The <code>wts</code> argument for some contrast methods. You should omit this argument unless you want unequal <code>wts</code> . Otherwise we recommend specifying <code>wts = NA</code> which instructs that <code>wts</code> be obtained from object, <i>separately</i> for each by group. If numerical <code>wts</code> are specified, they must conform to the number of levels in each by group, and those same weights are used in each group.
<code>x</code>	An <code>emmGrid</code> object
<code>reverse</code>	Logical value - determines whether to use "pairwise" (if TRUE) or "revpairwise" (if FALSE).

Value

`contrast` and `pairs` return an object of class `emmGrid`. Its grid will correspond to the levels of the contrasts and any by variables. The exception is that an `emm_list` object is returned if `simple` is a list and `combine` is FALSE.

`coef` returns a data.frame containing the "parent" object's grid, along with columns named `c.1`, `c.2`, ... containing the contrast coefficients used to produce the linear functions embodied in the object. `coef()` only returns coefficients if object is the result of a call to `contrast()`, and the parent object is the object that was handed to `contrast`. This is most useful for understanding interaction contrasts.

`weights` returns the weights stored for each row of object, or a vector of 1s if no weights are saved.

Pairs method

The call `pairs(object)` is equivalent to `contrast(object, method = "pairwise")`; and `pairs(object, reverse = TRUE)` is the same as `contrast(object, method = "revpairwise")`.

Interaction contrasts

When `interaction` is specified, interaction contrasts are computed. Specifically contrasts are generated for each factor separately, one at a time; and these contrasts are applied to the object (the first time around) or to the previous result (subsequently). (Any factors specified in by are skipped.) The final result comprises contrasts of contrasts, or, equivalently, products of contrasts for the factors involved. Any named elements of `interaction` are assigned to contrast methods; others are assigned in order of appearance in `object@levels`. The contrast factors in the resulting `emmGrid` object are ordered the same as in `interaction`.

`interaction` may be a character vector or list of valid contrast methods (as documented for the `method` argument). If the vector or list is shorter than the number needed, it is recycled. Alternatively, if the user specifies `contrast = TRUE`, the contrast specified in `method` is used for all factors involved.

Simple contrasts

simple is essentially the complement of by: When simple is a character vector, by is set to all the factors in the grid *except* those in simple. If simple is a list, each element is used in turn as simple, and assembled in an "emm_list". To generate *all* simple main effects, use simple = "each" (this works unless there actually is a factor named "each"). Note that a non-missing simple will cause by to be ignored.

Ordinarily, when simple is a list or "each", the return value is an `emm_list` object with each entry in correspondence with the entries of simple. However, with `combine = TRUE`, the elements are all combined into one family of contrasts in a single `emmGrid` object using `rbind.emmGrid`. In that case, the `adjust` argument sets the adjustment method for the combined set of contrasts.

Note

When object has a nesting structure (this can be seen via `str(object)`), then any grouping factors involved are forced into service as by variables, and the contrasts are thus computed separately in each nest. This in turn may lead to an irregular grid in the returned `emmGrid` object, which may not be valid for subsequent `emmeans` calls.

Examples

```
warp.lm <- lm(breaks ~ wool*tension, data = warpbreaks)
(warp.emm <- emmeans(warp.lm, ~ tension | wool))

contrast(warp.emm, "poly") # inherits 'by = "wool"' from warp.emm

### Custom contrast coefs (we already have wool as 'by' thus 3 means to contrast)
contrast(warp.emm, list(mid.vs.ends = c(-1,2,-1)/2, lo.vs.hi = c(1,0,-1)))

pairs(warp.emm)

# Effects (dev from mean) of the 6 factor combs, with enhanced levels:
contrast(warp.emm, "eff", by = NULL,
         enhance.levels = c("wool", "tension"))

pairs(warp.emm, simple = "wool") # same as pairs(warp.emm, by = "tension")

# Do all "simple" comparisons, combined into one family
pairs(warp.emm, simple = "each", combine = TRUE)

## Not run:

## Note that the following are NOT the same:
contrast(warp.emm, simple = c("wool", "tension"))
contrast(warp.emm, simple = list("wool", "tension"))
## The first generates contrasts for combinations of wool and tension
## (same as by = NULL)
## The second generates contrasts for wool by tension, and for
## tension by wool, respectively.

## End(Not run)
```

```

# An interaction contrast for tension:wool
tw.emm <- contrast(warp.emm, interaction = c(tension = "poly", wool = "consec"),
                  by = NULL)
tw.emm      # see the estimates
coef(tw.emm) # see the contrast coefficients

# Use of scale and offset
# an unusual use of the famous stack-loss data...
mod <- lm(Water.Temp ~ poly(stack.loss, degree = 2), data = stackloss)
(emm <- emmeans(mod, "stack.loss", at = list(stack.loss = 10 * (1:4))))
# Convert results from Celsius to Fahrenheit:
confint(contrast(emm, "identity", scale = 9/5, offset = 32))

```

contrast-methods *Contrast families*

Description

Functions with an extension of `.emmc` provide for named contrast families. One of the standard ones documented here may be used, or the user may write such a function.

Usage

```

pairwise.emmc(levs, exclude = integer(0), include, ...)

revpairwise.emmc(levs, exclude = integer(0), include, ...)

tukey.emmc(levs, reverse = FALSE, ...)

poly.emmc(levs, max.degree = min(6, k - 1), ...)

opoly.emmc(levs, max.degree = min(6, k - 1), scores, exclude = integer(0),
            include, ...)

trt.vs.ctrl.emmc(levs, ref = 1, reverse = FALSE, exclude = integer(0),
                 include, ...)

trt.vs.ctrl1.emmc(levs, ref = 1, ...)

trt.vs.ctrlk.emmc(levs, ref = length(levs), ...)

dunnett.emmc(levs, ref = 1, ...)

eff.emmc(levs, exclude = integer(0), include, wts = rep(1, length(levs)),
         ...)

del.eff.emmc(levs, exclude = integer(0), include, wts = rep(1,

```

```

length(levs)), ...)

consec.emmc(levs, reverse = FALSE, exclude = integer(0), include, ...)

mean_chg.emmc(levs, reverse = FALSE, exclude = integer(0), include, ...)

helmert.emmc(levs, exclude = integer(0), include, ...)

nrmlz.emmc(levs, family, ...)

wtcon.emmc(levs, wts = rep(1, length(levs)), cmtype = "GrandMean", ...)

identity.emmc(levs, exclude = integer(0), include, ...)

```

Arguments

<code>levs</code>	Vector of factor levels
<code>exclude</code>	integer vector of indices, or character vector of levels to exclude from consideration. These levels will receive weight 0 in all contrasts. Character levels must exactly match elements of <code>levs</code> .
<code>include</code>	integer or character vector of levels to include (the complement of <code>exclude</code>). An error will result if the user specifies both <code>exclude</code> and <code>include</code> .
<code>...</code>	Additional arguments, passed to related methods as appropriate
<code>reverse</code>	Logical value to determine the direction of comparisons
<code>max.degree</code>	Integer specifying the maximum degree of polynomial contrasts
<code>scores</code>	Set of values of length <code>length(levs)</code> over which orthogonal polynomials are computed. The default scores are the consecutive integers <code>seq_along(levs)</code> . (If <code>exclude</code> or <code>include</code> are used, the default scores are subsetted accordingly; and if <code>scores</code> is specified, its length must be the same as that of the subsetted <code>levs</code>).
<code>ref</code>	Integer(s) or character(s) specifying which level(s) to use as the reference. Character values must exactly match elements of <code>levs</code> (including any enhancements – see examples)
<code>wts</code>	Optional weights to use with <code>eff.emmc</code> and <code>del.eff.emmc</code> contrasts. These default to equal weights. If <code>exclude</code> or <code>include</code> are specified, <code>wts</code> may be either the same length as <code>levs</code> or the length of the included levels. In the former case, weights for any excluded levels are set to zero. <code>wts</code> has no impact on the results unless there are at least three levels included in the contrast.
<code>family</code>	name of contrast family to use
<code>cmtype</code>	the type argument passed to <code>contrMat</code>

Details

Each standard contrast family has a default multiple-testing adjustment as noted below. These adjustments are often only approximate; for a more exacting adjustment, use the interfaces provided to `glht` in the **multcomp** package.

`pairwise.emmc`, `revpairwise.emmc`, and `tukey.emmc` generate contrasts for all pairwise comparisons among estimated marginal means at the levels in `levs`. The distinction is in which direction they are subtracted. For factor levels A, B, C, D, `pairwise.emmc` generates the comparisons A-B, A-C, A-D, B-C, B-D, and C-D, whereas `revpairwise.emmc` generates B-A, C-A, C-B, D-A, D-B, and D-C. `tukey.emmc` invokes `pairwise.emmc` or `revpairwise.emmc` depending on `reverse`. The default multiplicity adjustment method is "tukey", which is only approximate when the standard errors differ.

`poly.emmc` and `opoly.emmc` generate orthogonal polynomial contrasts. `poly.emmc` uses equally-spaced factor levels; coefficients are derived from the `poly` function, but an *ad hoc* algorithm is used to scale them to integer coefficients that are (usually) the same as in published tables of orthogonal polynomial contrasts. On the other hand, `opoly.emmc`'s coefficients are always normalized (sum of squares equals 1), but allows the user to choose alternate reference points in scores, as in the `contr.poly` function. In both cases, the default multiplicity adjustment method is "none".

`trt.vs.ctrl.emmc` and its relatives generate contrasts for comparing one level (or the average over specified levels) with each of the other levels. The argument `ref` should be the index(es) (not the labels) of the reference level(s). `trt.vs.ctrl1.emmc` is the same as `trt.vs.ctrl.emmc` with a reference value of 1, and `trt.vs.ctrlk.emmc` is the same as `trt.vs.ctrl` with a reference value of `length(levs)`. `dunnett.emmc` is the same as `trt.vs.ctrl`. The default multiplicity adjustment method is "dunnett", a close approximation to the Dunnett adjustment. *Note* in all of these functions, it is illegal to have any overlap between the `ref` levels and the `exclude` levels. If any is found, an error is thrown.

`consec.emmc` and `mean_chg.emmc` are useful for contrasting treatments that occur in sequence. For a factor with levels A, B, C, D, `consec.emmc` generates the comparisons B-A, C-B, and D-C, while `mean_chg.emmc` generates the contrasts $(B+C+D)/3 - A$, $(C+D)/2 - (A+B)/2$, and $D - (A+B+C)/3$. With `reverse = TRUE`, these differences go in the opposite direction.

`eff.emmc` and `del.eff.emmc` generate contrasts that compare each level with the average over all levels (in `eff.emmc`) or over all other levels (in `del.eff.emmc`). These differ only in how they are scaled. For a set of k EMMs, `del.eff.emmc` gives weight 1 to one EMM and weight $-1/(k-1)$ to the others, while `eff.emmc` gives weights $(k-1)/k$ and $-1/k$ respectively, as in subtracting the overall EMM from each EMM. The default multiplicity adjustment method is "fdr". This is a Bonferroni-based method and is slightly conservative; see `p.adjust`.

`nrmlz.emmc` is a wrapper that can be used with any other `.emmc` function that will normalize the contrast coefficients so that the sum of its squares equals 1. Just provide the root name of the function in `family`, along with any other arguments to pass to it.

`wtcon.emmc` generates weighted contrasts based on the function `contrMat` function in the **multcomp** package, using the provided `type` as documented there. If the user provides `wts`, they have to conform to the length of `levs`; however, if `wts` is not specified, `contrast` will fill-in what is required, and usually this is safer (especially when by `!= NULL` which usually means that the weights are different in each by group).

`identity.emmc` simply returns the identity matrix (as a data frame), minus any columns specified in `exclude`. It is potentially useful in cases where a contrast function must be specified, but none is desired.

Value

A data.frame, each column containing contrast coefficients for `levs`. The "desc" attribute is used to label the results in `emmeans`, and the "adjust" attribute gives the default adjustment method for

multiplicity.

Note

Caution is needed in cases where the user alters the ordering of results (e.g., using the the "[...]" operator), because the contrasts generated depend on the order of the levels provided. For example, suppose `trt.vs.ctrl1` contrasts are applied to two by groups with levels ordered (Ctrl, T1, T2) and (T1, T2, Ctrl) respectively, then the contrasts generated will be for (T1 - Ctrl, T2 - Ctrl) in the first group and (T2 - T1, Ctrl - T1) in the second group, because the first level in each group is used as the reference level.

Examples

```
warp.lm <- lm(breaks ~ wool*tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)
contrast(warp.emm, "poly")
contrast(warp.emm, "trt.vs.ctrl1", ref = "M")
## Not run:
## Same when enhanced labeling is used:
contrast(warp.emm, "trt.vs.ctrl1",
         enhance.levels = "tension", ref = "tensionM")
## End(Not run)

# Comparisons with grand mean
contrast(warp.emm, "eff")
# Comparisons with a weighted grand mean
contrast(warp.emm, "eff", wts = c(2, 5, 3))

# Compare only low and high tensions
# Note pairs(emm, ...) calls contrast(emm, "pairwise", ...)
pairs(warp.emm, exclude = 2)
# (same results using exclude = "M" or include = c("L","H") or include = c(1,3))

# Same contrasts as above but with normalized contrast coefficients
contrast(warp.emm, "nrmlz", family = "pairwise", include = c(1, 3))

### Setting up a custom contrast function
revhelmert.emmc <- function(levs, ...) {
  M <- as.data.frame(contr.helmert(levs)[rev(seq_along(levs)), ])
  names(M) <- paste(rev(levs)[-1], "vs later")
  attr(M, "desc") <- "reverse Helmert contrasts"
  M
}
contrast(warp.emm, "revhelmert")

## Not run:
# See what is used for polynomial contrasts with 6 levels
emmeans:::poly.emmc(1:6)

## End(Not run)
```

eff_size Calculate Cohen effect sizes and confidence bounds thereof

Description

Standardized effect sizes are typically calculated using pairwise differences of estimates, divided by the SD of the population providing the context for those effects. This function calculates effect sizes from an `emmGrid` object, and confidence intervals for them, accounting for uncertainty in both the estimated effects and the population SD.

Usage

```
eff_size(object, sigma, edf, method = "pairwise", ...)
```

Arguments

<code>object</code>	an <code>emmGrid</code> object, typically one defining the EMMs to be contrasted. If instead, <code>class(object) == "emm_list"</code> , such as is produced by <code>emmeans(model, pairwise ~ treatment)</code> , a message is displayed; the contrasts already therein are used; and <code>method</code> is replaced by "identity".
<code>sigma</code>	numeric scalar, value of the population SD.
<code>edf</code>	numeric scalar that specifies the equivalent degrees of freedom for the <code>sigma</code> . This is a way of specifying the uncertainty in <code>sigma</code> , in that we regard our estimate of <code>sigma^2</code> as being proportional to a chi-square random variable with <code>edf</code> degrees of freedom. (<code>edf</code> should not be confused with the <code>df</code> argument that may be passed via <code>...</code> to specify the degrees of freedom to use in <i>t</i> statistics and confidence intervals.)
<code>method</code>	the contrast method to use to define the effects. This is passed to <code>contrast</code> after the elements of <code>object</code> are scaled.
<code>...</code>	Additional arguments passed to <code>contrast</code>

Details

Any by variables specified in `object` will remain in force in the returned effects, unless overridden in the optional arguments.

For models having a single random effect, such as those fitted using `lm`; in that case, the `stats::sigma` and `stats::df.residual` functions may be useful for specifying `sigma` and `edf`. For models with more than one random effect, `sigma` may be based on some combination of the random-effect variances.

Specifying `edf` can be rather unintuitive but is also relatively uncritical; but the smaller the value, the wider the confidence intervals for effect size. The value of $\sqrt{2/edf}$ can be interpreted as the relative accuracy of `sigma`; for example, with `edf = 50`, $\sqrt{2/50} = 0.2$, meaning that `sigma` is accurate to plus or minus 20 percent. Note in an example below, we tried two different `edf` values as kind of a bracketing/sensitivity-analysis strategy. A value of `Inf` is allowable, in which case you are assuming that `sigma` is known exactly. Obviously, this narrows the confidence intervals for the effect sizes – unrealistically if in fact `sigma` is unknown.

Value

an `emmGrid` object containing the effect sizes

Computation

This function uses calls to `regrid` to put the estimated marginal means (EMMs) on the log scale. Then an extra element is added to this grid for the log of `sigma` and its standard error (where we assume that `sigma` is uncorrelated with the log EMMs). Then a call to `contrast` subtracts $\log\{\sigma\}$ from each of the log EMMs, yielding values of $\log(\text{EMM}/\sigma)$. Finally, the results are re-gridded back to the original scale and the desired contrasts are computed using `method`. In the log-scaling part, we actually rescale the absolute values and keep track of the signs.

Note

The effects are always computed on the scale of the *linear-predictor*; any response transformation or link function is completely ignored. If you wish to base the effect sizes on the response scale, it is *not* enough to replace `object` with `regrid(object)`, because this back-transformation changes the SD required to compute effect sizes.

Paired data: Be careful with paired-data situations, where Cohen's *d* is typically referenced to the SD of the *paired differences* rather than the *residual* SD. You may need to enlarge `sigma` by a factor of $\sqrt{2}$ to obtain comparable results with other software.

Disclaimer: There is substantial disagreement among practitioners on what is the appropriate `sigma` to use in computing effect sizes; or, indeed, whether *any* effect-size measure is appropriate for some situations. The user is completely responsible for specifying appropriate parameters (or for failing to do so).

Cohen effect sizes do not even exist for generalized linear models or other models lacking an additive residual error term.

The examples here illustrate a sobering message that effect sizes are often not nearly as accurate as you may think.

Examples

```
fiber.lm <- lm(strength ~ diameter + machine, data = fiber)

emm <- emmeans(fiber.lm, "machine")
eff_size(emm, sigma = sigma(fiber.lm), edf = df.residual(fiber.lm))

# or equivalently:
eff_size(pairs(emm), sigma(fiber.lm), df.residual(fiber.lm), method = "identity")

### Mixed model example:
if (require(nlme)) withAutoprint({
  Oats.lme <- lme(yield ~ Variety + factor(nitro),
    random = ~ 1 | Block / Variety,
    data = Oats)
  # Combine variance estimates
  VarCorr(Oats.lme)
  (totSD <- sqrt(214.4724 + 109.6931 + 162.5590))
})
```

```
# I figure edf is somewhere between 5 (Blocks df) and 51 (Resid df)
emmV <- emmeans(Oats.lme, ~ Variety)
eff_size(emmV, sigma = totSD, edf = 5)
eff_size(emmV, sigma = totSD, edf = 51)
}, spaced = TRUE)
```

 emm

Support for multcomp::glht

Description

These functions and methods provide an interface between **emmeans** and the `multcomp::glht` function for simultaneous inference provided by the **multcomp** package.

Usage

```
emm(...)

as.glht(object, ...)

## S3 method for class 'emmGrid'
as.glht(object, ...)
```

Arguments

<code>...</code>	In <code>emm</code> , the <code>specs</code> , <code>by</code> , and <code>contr</code> arguments you would normally supply to emmeans . Only <code>specs</code> is required. Otherwise, arguments are passed to other methods. You may also include a <code>which</code> argument; see Details .
<code>object</code>	An object of class <code>emmGrid</code> or <code>emm_list</code>

Value

`emm` returns an object of an intermediate class for which there is a `multcomp::glht` method.

`as.glht` returns an object of class `glht` or `glht_list` according to whether `object` is of class `emmGrid` or `emm_list`. See [Details](#) below for more on `glht_lists`.

Details for `emm`

`emm` is meant to be called only *from* "glht" as its second (`linfct`) argument. It works similarly to `multcomp::mcp`, except with `specs` (and optionally `by` and `contr` arguments) provided as in a call to [emmeans](#).

If the specifications in `...` would result in a list (i.e., an `emm_list` object), then by default, only the last element of that list is passed to `glht`. However, if `...` contains a `which` argument consisting of integer values, the list elements with those indexes are selected and combined and passed on to `glht`. No checking is done on whether the indexes are valid, and the keyword `which` must be spelled-out.

Details for as.glht

When no by variable is in force, we obtain a `glht` object; otherwise it is a `glht_list`. The latter is defined in **emmeans**, not **multcomp**, and is simply a list of `glht` objects. Appropriate convenience methods `coef`, `confint`, `plot`, `summary`, and `vcov` are provided, which simply apply the corresponding `glht` methods to each member.

Note

The multivariate-*t* routines used by `glht` require that all estimates in the family have the same integer degrees of freedom. In cases where that is not true, a message is displayed that shows what `df` is used. The user may override this via the `df` argument.

Examples

```
if(require(multcomp, quietly = TRUE))
  emm_example("glht-multcomp")
  # Use emm_example("glht-multcomp", list = TRUE) # to see just the code
```

emmeans

Estimated marginal means (Least-squares means)

Description

Compute estimated marginal means (EMMs) for specified factors or factor combinations in a linear model; and optionally, comparisons or contrasts among them. EMMs are also known as least-squares means.

Usage

```
emmeans(object, specs, by = NULL, fac.reduce = function(coefs) apply(coefs,
  2, mean), contr, options = get_emm_option("emmeans"), weights, offset, ...,
  tran)
```

Arguments

<code>object</code>	An object of class <code>emmGrid</code> ; or a fitted model object that is supported, such as the result of a call to <code>lm</code> or <code>lmer</code> . Many fitted-model objects are supported; see vignette("models", "emmeans") for details.
<code>specs</code>	A character vector specifying the names of the predictors over which EMMs are desired. <code>specs</code> may also be a formula or a list (optionally named) of valid specs. Use of formulas is described in the Overview section below. Specifying <code>.</code> as the only factor name creates a list of specifications for all model terms. Note: We recommend <i>against</i> using two-sided formulas; see the note below for <code>contr</code> .
<code>by</code>	A character vector specifying the names of predictors to condition on.

fac.reduce	A function that combines the rows of a matrix into a single vector. This implements the “marginal averaging” aspect of EMMs. The default is the mean of the rows. Typically if it is overridden, it would be some kind of weighted mean of the rows. If fac.reduce is nonlinear, bizarre results are likely, and EMMs will not be interpretable. NOTE: If the weights argument is non-missing, fac.reduce is ignored.
contr	A character value or list specifying contrasts to be added. See contrast . Note: contr is ignored when specs is a formula. Note 2: We recommend <i>against</i> using this argument; obtaining means and obtaining contrasts are two different things, and it is best to do them in separate steps, using the contrast function for the contrasts.
options	If non-NULL, a named list of arguments to pass to update.emmGrid , just after the object is constructed. (Options may also be included in <code>...</code> ; see the ‘options’ section below.)
weights	Character value, numeric vector, or numeric matrix specifying weights to use in averaging predictions. See “Weights” section below. Also, if object is not already a reference grid, weights (if it is character) is passed to <code>ref_grid</code> as <code>wt.nuis</code> in case nuisance factors are specified. We can override this by specifying <code>wt.nuis</code> explicitly. This more-or-less makes the weighting of nuisance factors consistent with that of primary factors.
offset	Numeric vector or scalar. If specified, this adds an offset to the predictions, or overrides any offset in the model or its reference grid. If a vector of length differing from the number of rows in the result, it is subsetted or cyclically recycled.
...	When object is not already a “ <code>emmGrid</code> ” object, these arguments are passed to <code>ref_grid</code> . Common examples are <code>at</code> , <code>cov.reduce</code> , <code>data</code> , <code>type</code> , <code>regrid</code> , <code>df</code> , <code>nesting</code> , and <code>vcov..</code> Model-type-specific options (see vignette(“models”, “emmeans”)), commonly <code>mode</code> , may be used here as well. In addition, if the model formula contains references to variables that are not predictors, you must provide a <code>params</code> argument with a list of their names. These arguments may also be used in lieu of options. See the ‘Options’ section below.
tran	Placeholder to prevent it from being included in <code>...</code> . If non-missing, it is added to ‘options’. See the ‘Options’ section.

Details

Users should also consult the documentation for [ref_grid](#), because many important options for EMMs are implemented there, via the `...` argument.

Value

When `specs` is a character vector or one-sided formula, an object of class “`emmGrid`”. A number of methods are provided for further analysis, including [summary.emmGrid](#), [confint.emmGrid](#), [test.emmGrid](#), [contrast.emmGrid](#), and [pairs.emmGrid](#). When `specs` is a list or a formula having a left-hand side, the return value is an `emm_list` object, which is simply a list of `emmGrid` objects.

Overview

Estimated marginal means or EMMs (sometimes called least-squares means) are predictions from a linear model over a *reference grid*; or marginal averages thereof. The `ref_grid` function identifies/creates the reference grid upon which `emmeans` is based.

For those who prefer the terms “least-squares means” or “predicted marginal means”, functions `lsmeans` and `pmmeans` are provided as wrappers. See [wrappers](#).

If `specs` is a formula, it should be of the form `~ specs`, `~ specs | by`, `contr ~ specs`, or `contr ~ specs | by`. The formula is parsed and the variables therein are used as the arguments `specs`, `by`, and `contr` as indicated. The left-hand side is optional (and we don’t recommend it), but if specified it should be the name of a contrast family (e.g., `pairwise`). Operators like `*` or `:` are needed in the formula to delineate names, but otherwise are ignored.

We now also allow using `.` in `specs`. If this is done, we run `joint_tests` on the side to determine all relevant model terms, then replace `specs` with a corresponding list of specifications. This is a convenience, but it can create a sizeable `emm_list` object and it is coded rather inefficiently. While it is permissible to include contrasts via a `contr` argument or formula left-hand-side, we recommend instead doing this in a follow-up test with `contrast.emm_list`. *Caution:* In models with nested fixed effects, using `.` creates results where nested factors interact with nesting factors; in those cases, any contrasts you specify will go across nests, which is likely not what is desired.

In the special case where the mean (or weighted mean) of all the predictions is desired, specify `specs` as `~ 1` or `"1"`.

A number of standard contrast families are provided. They can be identified as functions having names ending in `.emmc` – see the documentation for [emmc-functions](#) for details – including how to write your own `.emmc` function for custom contrasts.

Weights

If `weights` is a vector, its length must equal the number of predictions to be averaged to obtain each EMM. If a matrix, each row of the matrix is used in turn, wrapping back to the first row as needed. When in doubt about what is being averaged (or how many), first call `emmeans` with `weights = "show.levels"`.

If `weights` is a string, it should partially match one of the following:

`"equal"` Use an equally weighted average.

`"proportional"` Weight in proportion to the frequencies (in the original data) of the factor combinations that are averaged over.

`"outer"` Weight in proportion to each individual factor’s marginal frequencies. Thus, the weights for a combination of factors are the outer product of the one-factor margins

`"cells"` Weight according to the frequencies of the cells being averaged.

`"flat"` Give equal weight to all cells with data, and ignore empty cells.

`"show.levels"` This is a convenience feature for understanding what is being averaged over. Instead of a table of EMMs, this causes the function to return a table showing the levels that are averaged over, in the order that they appear.

Outer weights are like the ‘expected’ counts in a chi-square test of independence, and will yield the same results as those obtained by proportional averaging with one factor at a time. All except

"cells" uses the same set of weights for each mean. In a model where the predicted values are the cell means, cell weights will yield the raw averages of the data for the factors involved. Using "flat" is similar to "cells", except nonempty cells are weighted equally and empty cells are ignored.

Counterfactuals

Counterfactual reference grids (see the documentation for [ref_grid](#)) contain pairs of imputed and actual factor levels, and are handled in a special way. For starters, the `weights` argument is ignored and we always use "cells" weights. Our understanding is that if factors A, B are specified as counterfactuals, the marginal means for A should still be the same as if A were the only counterfactual. Accordingly, in computing these marginal means, we exclude all cases where $B \neq \text{actual}_B$, because if A were the only counterfactual, B will stay at its actual level. We also take special pains to "remember" information about actual and imputed levels of counterfactuals so that appropriate results are obtained when `emmeans` is applied to a previous `emmeans` result.

Offsets

Unlike in `ref_grid`, an offset need not be scalar. If not enough values are supplied, they are cyclically recycled. For a vector of offsets, it is important to understand that the ordering of results goes with the first name in `specs` varying fastest. If there are any by factors, those vary slower than all the primary ones, but the first by variable varies the fastest within that hierarchy. See the examples.

Options and ...

Arguments that could go in options may instead be included in ..., typically, arguments such as `type`, `infer`, etc. that in essence are passed to `summary.emmGrid`. Arguments in both places are overridden by the ones in ...

There is a danger that ... arguments could partially match those used by both `ref_grid` and `update.emmGrid`, creating a conflict. If these occur, usually they can be resolved by providing complete (or at least longer) argument names; or by isolating non-`ref_grid` arguments in options; or by calling `ref_grid` separately and passing the result as object. See a not-run example below.

Also, when `specs` is a two-sided formula, or `contr` is specified, there is potential confusion concerning which ... arguments apply to the means, and which to the contrasts. When such confusion is possible, we suggest doing things separately (a call to `emmeans` with no contrasts, followed by a call to `contrast`). We treat `adjust` as a special case: it is applied to the `emmeans` results *only* if there are no contrasts specified, otherwise it is passed only to `contrast`.

See Also

[ref_grid](#), [contrast](#), [vignette\("models", "emmeans"\)](#)

Examples

```
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
emmeans(warp.lm, ~ wool | tension)
# or equivalently emmeans(warp.lm, "wool", by = "tension")
```

```

# 'adjust' argument ignored in emmeans, passed to contrast part...
emmeans (warp.lm, poly ~ tension | wool, adjust = "sidak")

# 'adjust' argument NOT ignored ...
emmeans (warp.lm, ~ tension | wool, adjust = "sidak")

# Get all sets of EMMs for this model
( allsets <- emmeans(warp.lm, ".") )
contrast(allsets, "eff") # all effects

## Not run:
### Offsets: Consider a silly example:
emmeans(warp.lm, ~ tension | wool, offset = c(17, 23, 47)) @ grid
# note that offsets are recycled so that each level of tension receives
# the same offset for each wool.
# But using the same offsets with ~ wool | tension will probably not
# be what you want because the ordering of combinations is different.

## End(Not run)

```

 emmGrid-class

The emmGrid class

Description

The `emmGrid` class encapsulates linear functions of regression parameters, defined over a grid of predictors. This includes reference grids and grids of marginal means thereof (aka estimated marginal means). Objects of class ‘`emmGrid`’ may be used independently of the underlying model object. Instances are created primarily by `ref_grid` and `emmeans`, and several related functions.

Slots

- `model.info` list. Contains the elements `call` (the call that produced the model), `terms` (its terms object), and `xlev` (factor-level information)
- `roles` list. Contains at least the elements `predictors`, `responses`, and `multresp`. Each is a character vector of names of these variables.
- `grid` data.frame. Contains the combinations of the variables that define the reference grid. In addition, there is an auxiliary column named `".wgt."` holding the observed frequencies or weights for each factor combination (excluding covariates). If the model has one or more `offset()` calls, there is an another auxiliary column named `".offset."`. Auxiliary columns are not considered part of the reference grid. (However, any variables included in `offset` calls *are* in the reference grid.)
- `levels` list. Each entry is a character vector with the distinct levels of each variable in the reference grid. Note that `grid` is obtained by applying the function `expand.grid` to this list
- `matlevs` list. Like `levels` but has the levels of any matrices in the original dataset. Matrix columns are always concatenated and treated as a single variable for purposes of the reference grid

- `linfct` matrix. Each row consists of the linear function of the regression coefficients for predicting its corresponding element of the reference grid. The rows of this matrix go in one-to-one correspondence with the rows of `grid`, and the columns with elements of `bhat`.
- `bhat` numeric. The regression coefficients. If there is a multivariate response, the matrix of coefficients is flattened to a single vector, and `linfct` and `V` redefined appropriately. Important: `bhat` must *include* any NA values produced as a result of collinearity in the predictors. These are taken care of later in the estimability check.
- `nbasis` matrix. The basis for the non-estimable functions of the regression coefficients. Every EMM will correspond to a linear combination of rows of `linfct`, and that result must be orthogonal to all the columns of `nbasis` in order to be estimable. If everything is estimable, `nbasis` should be a 1 x 1 matrix of NA.
- `V` matrix. The symmetric variance-covariance matrix of `bhat`
- `dffun` function having two arguments. `dffun(k, dfargs)` should return the degrees of freedom for the linear function `sum(k*bhat)`, or NA if unavailable
- `dfargs` list. Used to hold any additional information needed by `dffun`.
- `misc` list. Additional information used by methods. These include at least the following: `estName` (the label for the estimates of linear functions), and the default values of `infer`, `level`, and `adjust` to be used in the `summary.emmGrid` method. Elements in this slot may be modified if desired using the `update.emmGrid` method.
- `post.beta` matrix. A sample from the posterior distribution of the regression coefficients, if MCMC methods were used; or a 1 x 1 matrix of NA otherwise. When it is non-trivial, the `as.mcmc.emmGrid` method returns `post.beta %>% t(linfct)`, which is a sample from the posterior distribution of the EMMs.

Methods

All methods for these objects are S3 methods except for `show`. They include `[.emmGrid`, `as.glt.emmGrid`, `as.mcmc.emmGrid`, `as.mcmc.list.emmGrid` (see `coda`), `cld.emmGrid` (see `multcomp`), `coef.emmGrid`, `confint.emmGrid`, `contrast.emmGrid`, `pairs.emmGrid`, `plot.emmGrid`, `predict.emmGrid`, `print.emmGrid`, `rbind.emmGrid`, `show.emmGrid`, `str.emmGrid`, `summary.emmGrid`, `test.emmGrid`, `update.emmGrid`, `vcov.emmGrid`, and `xtable.emmGrid`

emmip

Interaction-style plots for estimated marginal means

Description

Creates an interaction plot of EMMs based on a fitted model and a simple formula specification.

Usage

```
emmip(object, formula, ...)
```

```
## Default S3 method:
```

```
emmip(object, formula, type, CIs = FALSE, PIs = FALSE,
```

```

style, engine = get_emm_option("graphics.engine"), plotit = TRUE,
nesting.order = FALSE, abbr.len = c(0, 0), ...)

emmip_ggplot(emms, style = "factor", dodge = 0.2, xlab = labs$xlab,
ylab = labs$ylab, tlab = labs$tlab, facetlab = "label_both", scale,
dotarg = list(shape = "circle"), linearg = list(linetype = "solid"),
CIarg = list(alpha = 0.4), PIarg = list(alpha = 0.25), col = NULL, ...)

emmip_lattice(emms, style = "factor", xlab = labs$xlab, ylab = labs$ylab,
tlab = labs$tlab, pch = c(1, 2, 6, 7, 9, 10, 15:20), lty = 1,
col = NULL, ...)

```

Arguments

object	An object of class <code>emmGrid</code> , or a fitted model of a class supported by the emmeans package
formula	Formula of the form <code>trace.factors ~ x.factors by.factors</code> . The EMMs are plotted against <code>x.factor</code> for each level of <code>trace.factors</code> . <code>by.factors</code> is optional, but if present, it determines separate panels. Each element of this formula may be a single factor in the model, or a combination of factors using the <code>*</code> operator.
...	Additional arguments passed to <code>emmeans</code> (when <code>object</code> is not already an <code>emmGrid</code> object), <code>predict.emmGrid</code> , <code>emmip_ggplot</code> , or <code>emmip_lattice</code> .
type	As in <code>predict.emmGrid</code> , this determines whether we want to inverse-transform the predictions (<code>type = "response"</code>) or not (any other choice). The default is <code>"link"</code> , unless the <code>"predict.type"</code> option is in force; see <code>emm_options</code> . In addition, the user may specify <code>type = "scale"</code> to create a transformed scale for the vertical axis based on <code>object</code> 's response transformation or link function.
CI	Logical value. If <code>TRUE</code> , confidence intervals (or HPD intervals for Bayesian models) are added to the plot (works only with <code>engine = "ggplot"</code>).
PI	Logical value. If <code>TRUE</code> , prediction intervals are added to the plot (works only with <code>engine = "ggplot"</code>). This is allowed only if the underlying model family is <code>"gaussian"</code> . If both <code>CI</code> s and <code>PI</code> s are <code>TRUE</code> , the prediction intervals will be somewhat longer, lighter, and thinner than the confidence intervals. Additional parameters to <code>predict.emmGrid</code> (e.g., <code>sigma</code>) may be passed via <code>...</code> . For Bayesian models, <code>PI</code> s require <code>frequentist = TRUE</code> and a value for <code>sigma</code> .
style	Optional character value. This has an effect only when the horizontal variable is a single numeric variable. If <code>style</code> is unspecified or <code>"numeric"</code> , the horizontal scale will be numeric and curves are plotted using lines (and no symbols). With <code>style = "factor"</code> , the horizontal variable is treated as the levels of a factor (equally spaced along the horizontal scale), and curves are plotted using lines and symbols. When the horizontal variable is character or factor, or a combination of more than one predictor, <code>"factor"</code> style is always used.
engine	Character value matching <code>"ggplot"</code> (default), <code>"lattice"</code> , or <code>"none"</code> . The graphics engine to be used to produce the plot. These require, respectively, the ggplot2 or lattice package to be installed. Specifying <code>"none"</code> is equivalent to setting <code>plotit = FALSE</code> .

<code>plotit</code>	Logical value. If TRUE, a graphical object is returned; if FALSE, a <code>data.frame</code> is returned containing all the values used to construct the plot.
<code>nesting.order</code>	Logical value. If TRUE, factors that are nested are presented in order according to their nesting factors, even if those nesting factors are not present in formula. If FALSE, only the variables in formula are used to order the variables.
<code>abbr.len</code>	Integer vector of length 1 or 2 used to specify that factor levels be abbreviated to the specified lengths, using <code>abbreviate</code> . Any values less than 1 are ignored. <code>abbr.len[1]</code> applies to a factor plotted along the horizontal axis, and <code>abbr.len[2]</code> (if present) applies to trace factors (shown in a legend) or by factors (shown in facet labels).
<code>emms</code>	A <code>data.frame</code> created by calling <code>emmip</code> with <code>plotit = FALSE</code> . Certain variables and attributes are expected to exist in this data frame; see the section detailing the rendering functions.
<code>dodge</code>	Numerical amount passed to <code>ggplot2::position_dodge</code> by which points and intervals are offset so they do not collide.
<code>xlab, ylab, tlab</code>	Character labels for the horizontal axis, vertical axis, and traces (the different curves), respectively. The <code>emmip</code> function generates these automatically and provides them via the <code>labs</code> attribute, but the user may override these if desired.
<code>facetlab</code>	Labeller for facets (when by variables are in play). Use <code>"label_value"</code> to show just the factor levels, or <code>"label_both"</code> to show both the factor names and factor levels; <code>"label_context"</code> decides which based on how many by factors there are. See the documentation for <code>ggplot2::labellers</code> .
<code>scale</code>	If not missing, an object of class <code>scales::trans</code> specifying a (usually) nonlinear scaling for the vertical axis. For example, <code>scales = scales::log_trans()</code> specifies a logarithmic scale. For fine-tuning purposes, additional arguments to <code>ggplot2::scale_y_continuous</code> may be included in <code>...</code>
<code>dotarg</code>	list of arguments passed to <code>geom_point</code> to customize appearance of points. If this includes <code>shape</code> and it is of length greater than 1, it is interpreted as a shape palette instead.
<code>linearg</code>	list of arguments passed to <code>geom_line</code> to customize appearance of lines. If this includes <code>linetype</code> and it is of length greater than 1, it is interpreted as a <code>linetype</code> .
<code>CIarg, PIarg</code>	lists of arguments passed to <code>geom_linerange</code> to customize appearance of intervals. (Note: the <code>linetype</code> aesthetic defaults to <code>"solid"</code> under the hood)
<code>col</code>	With <code>emmip_ggplot</code> , this adds <code>color = col</code> (not <code>colour</code>) to all of the <code>*arg</code> lists. This is intended for setting a common color for everything, such as a black-and-white plot. With <code>emmip_lattice</code> , <code>col</code> specifies the colors to use for each group, recycled as needed. If not specified, the default trellis colors are used.
<code>pch</code>	(Lattice only) The plotting characters to use for each group (i.e., levels of <code>trace.factors</code>). They are recycled as needed.
<code>lty</code>	(Lattice only) The line types to use for each group. Recycled as needed.

Value

If `plotit = FALSE`, a `data.frame` (actually, a `summary_emm` object) with the table of EMMs that would be plotted. The variables plotted are named `xvar` and `yvar`, and the trace factor is named

tvar. This data frame has an added "labs" attribute containing the labels xlab, ylab, and tlab for these respective variables. The confidence limits are also included, renamed LCL and UCL.

If plotit = TRUE, the function returns an object of class "ggplot" or a "trellis", depending on engine.

Details

If object is a fitted model, [emmeans](#) is called with an appropriate specification to obtain estimated marginal means for each combination of the factors present in formula (in addition, any arguments in ... that match at, trend, cov.reduce, or fac.reduce are passed to emmeans). Otherwise, if object is an emmGrid object, its first element is used, and it must contain one estimate for each combination of the factors present in formula.

Rendering functions

The functions `emmip_ggplot` and `emmip_lattice` are called when `plotit == TRUE` to render the plots; but they may also be called later on an object saved via `plotit = FALSE` (or `engine = "none"`). The functions require that emms contains variables `xvar`, `yvar`, and `tvar`, and attributes "labs" and "vars". Confidence intervals are plotted if variables LCL and UCL exist; and prediction intervals are plotted if LPL and UPL exist. Finally, it must contain the variables named in `attr(emms, "vars")`.

In `emmip_ggplot`, colors, linetypes, and shapes are all assigned to groups (according to `tvar`) unless overridden. So, for example, one may have different symbols for each group by simply specifying `dotarg = list()`.

Note

Conceptually, this function is equivalent to [interaction.plot](#) where the summarization function is thought to return the EMMs.

See Also

[emmeans](#), [interaction.plot](#).

Examples

```
#--- Three-factor example
noise.lm = lm(noise ~ size * type * side, data = auto.noise)

# Separate interaction plots of size by type, for each side
emmip(noise.lm, type ~ size | side)

# Same using the "lattice" engine
emmip(noise.lm, type ~ size | side, engine = "lattice")

# One interaction plot, using combinations of size and side as the x factor
# ... with added confidence intervals and some formatting changes
emmip(noise.lm, type ~ side * size, CIs = TRUE,
      CIarg = list(linewidth = 1.5, alpha = 1, color = "orange"),
      dotarg = list(size = 2, shape = "square", color = "black"))
```

```

# Same using legacy theme
with_emm_options(gg.theme = 1,
  emmip(noise.lm, type ~ side * size, CIs = TRUE,
    CIarg = list(linewidth = 1.5, alpha = 1, color = "orange"),
    dotarg = list(size = 2, shape = "square", color = "black")))

# Create a black-and-white version of above with different linetypes
# (Let the linetypes and symbols default to the palette)
emmip(noise.lm, type ~ side * size, CIs = TRUE, col = "black",
  linearg = list(), dotarg = list(size = 4), CIarg = list(alpha = 1)) +
  ggplot2::theme_bw()

# One interaction plot using combinations of type and side as the trace factor
emmip(noise.lm, type * side ~ size)

# Individual traces in panels
emmip(noise.lm, ~ size | type * side)

# Example for the 'style' argument
fib.lm = lm(strength ~ machine * sqrt(diameter), data = fiber)
fib.rg = ref_grid(fib.lm, at = list(diameter = c(12, 14, 15, 25, 36)))
emmip(fib.rg, machine ~ diameter) # curves (because diameter is numeric)
emmip(fib.rg, machine ~ diameter, style = "factor") # points and lines

# For an example using extra ggplot2 code, see 'vignette("messy-data")',
# in the section on nested models.

### Options with transformations or link functions
neuralgia.glm <- glm(Pain ~ Treatment * Sex + Age, family = binomial(),
  data = neuralgia)

# On link scale:
emmip(neuralgia.glm, Treatment ~ Sex)

# On response scale:
emmip(neuralgia.glm, Treatment ~ Sex, type = "response")

# With transformed axis scale and custom scale divisions
emmip(neuralgia.glm, Treatment ~ Sex, type = "scale",
  breaks = seq(0.10, 0.90, by = 0.10))

```

Description

This allows the user to incorporate results obtained by some analysis into an `emmGrid` object, enabling the use of `emmGrid` methods to perform related follow-up analyses.

Usage

```
emmobj(bhat, V, levels, linfct = diag(length(bhat)), df = NA, dffun,
       dfargs = list(), post.beta = matrix(NA), nesting = NULL, se.bhat,
       se.diff, ...)
```

Arguments

bhat	Numeric. Vector of regression coefficients
V	Square matrix. Covariance matrix of bhat
levels	Named list or vector. Levels of factor(s) that define the estimates defined by linfct. If not a list, we assume one factor named "level"
linfct	Matrix. Linear functions of bhat for each combination of levels.
df	Numeric value or function with arguments (x, dfargs). If a number, that is used for the degrees of freedom. If a function, it should return the degrees of freedom for $\text{sum}(x \times \text{bhat})$, with any additional parameters in dfargs.
dffun	Overrides df if specified. This is a convenience to match the slot names of the returned object.
dfargs	List containing arguments for df. This is ignored if df is numeric.
post.beta	Matrix whose columns comprise a sample from the posterior distribution of the regression coefficients (so that typically, the column averages will be bhat). A 1 x 1 matrix of NA indicates that such a sample is unavailable.
nesting	Nesting specification as in ref_grid . This is ignored if <code>model.info</code> is supplied.
se.bhat, se.diff	Alternative way of specifying V. If <code>se.bhat</code> is specified, V is constructed using <code>se.bhat</code> , the standard errors of bhat, and <code>se.diffs</code> , the standard errors of its pairwise differences. <code>se.diff</code> should be a vector of length $k \times (k-1) / 2$ where k is the length of <code>se.bhat</code> , and its elements should be in the order 12, 13, ..., 1k, 23, ..., 2k, If <code>se.diff</code> is missing, V is computed as if the bhat are independent.
...	Arguments passed to update.emmGrid

Details

The arguments must be conformable. This includes that the length of `bhat`, the number of columns of `linfct`, and the number of columns of `post.beta` must all be equal. And that the product of lengths in `levels` must be equal to the number of rows of `linfct`. The grid slot of the returned object is generated by [expand_grid](#) using `levels` as its arguments. So the rows of `linfct` should be in corresponding order.

The functions `qdrgr` and `emmobj` are close cousins, in that they both produce `emmGrid` objects. When starting with summary statistics for an existing grid, `emmobj` is more useful, while `qdrgr` is more useful when starting from an unsupported fitted model.

Value

An `emmGrid` object

See Also

`qdrng`, an alternative that is useful when starting with a fitted model not supported in **emmeans**.

Examples

```
# Given summary statistics for 4 cells in a 2 x 2 layout, obtain
# marginal means and comparisons thereof. Assume heteroscedasticity
# and use the Satterthwaite method
levels <- list(trt = c("A", "B"), dose = c("high", "low"))
ybar <- c(57.6, 43.2, 88.9, 69.8)
s <- c(12.1, 19.5, 22.8, 43.2)
n <- c(44, 11, 37, 24)
se2 = s^2 / n
Satt.df <- function(x, dfargs)
  sum(x * dfargs$v)^2 / sum((x * dfargs$v)^2 / (dfargs$n - 1))

expt.emm <- emmobj(bhat = ybar, V = diag(se2),
  levels = levels, linfct = diag(c(1, 1, 1, 1)),
  df = Satt.df, dfargs = list(v = se2, n = n), estName = "mean")

( trt.emm <- emmeans(expt.emm, "trt") )
( dose.emm <- emmeans(expt.emm, "dose") )

rbind(pairs(trt.emm), pairs(dose.emm), adjust = "mvt")

### Create an emmobj from means and SEs
### (This illustration reproduces the MOats example for Variety = "Victory")
means = c(71.50000, 89.66667, 110.83333, 118.50000)
semeans = c(5.540591, 6.602048, 8.695358, 7.303221)
sediffs = c(7.310571, 9.894724, 7.463615, 10.248306, 4.935698, 8.694507)
foo = emmobj(bhat = means, se.bhat = semean, se.diff = sediffs,
  levels = list(nitro = seq(0, .6, by = .2)), df = 10)
plot(foo, comparisons = TRUE)
```

 emm_example

Run or list additional examples

Description

This function exists so as to provide cleaner-looking examples in help files when it must be run conditionally on another package. Typically we want to run the code (`run = TRUE` is the default), or otherwise just list it on the console (`list = TRUE`).

Usage

```
emm_example(name, run = !list, list = FALSE, ...)
```

Arguments

name	Character name of file to run. We look for a file with this name (with ".R" appended) in the system files provided with emmeans .
run	Logical choosing whether or not to run the example code
list	Logical choosing whether or not to list the example code
...	Used only by the developer

Examples

```
# List an example
emm_example("qdr-g-bigl", list = TRUE)

# Run an example
if (require(bigl))
  emm_example("qdr-g-bigl")
```

 emm_list

The emm_list class

Description

An `emm_list` object is simply a list of `emmGrid` objects. Such a list is returned, for example, by `emmeans` with a two-sided formula or a list as its `specs` argument. Several methods for this class are provided, as detailed below. Typically, these methods just quietly do the same thing as their `emmGrid` methods, using the first element of the list. You can specify which to select a different element, or just run the corresponding `emmGrid` method on `object[[k]]`.

Usage

```
## S3 method for class 'emm_list'
contrast(object, ..., which = NULL)

## S3 method for class 'emm_list'
pairs(x, ..., which = NULL)

## S3 method for class 'emm_list'
test(object, ..., which = seq_along(object))

## S3 method for class 'emm_list'
confint(object, ..., which = seq_along(object))

## S3 method for class 'emm_list'
plot(x, ..., which = 1)

## S3 method for class 'emm_list'
```

```

coef(object, ..., which = NULL)

## S3 method for class 'emm_list'
linfct(object, ..., which = seq_along(object))

## S3 method for class 'emm_list'
str(object, ...)

## S3 method for class 'emm_list'
summary(object, ..., which = seq_along(object))

## S3 method for class 'emm_list'
print(x, ...)

## S3 method for class 'emm_list'
as.data.frame(x, ...)

## S3 method for class 'summary_eml'
as.data.frame(x, row.names = NULL, optional = FALSE,
  which, ...)

```

Arguments

object, x	an object of class <code>emm_list</code>
...	additional arguments passed to corresponding <code>emmGrid</code> method. In addition, the user may include a logical argument <code>drop</code> that is akin to drop and the argument of the same name in subscripting matrices and data frames. When <code>drop</code> is <code>TRUE</code> (the default), then when the result is a list of length 1, the list structure is removed.
which	integer vector specifying which elements to select; if <code>NULL</code> , we try to guess which elements make sense. Usually, this is all elements having names that start with 'em' or 'ls', or the first element if no matches are found. However, in <code>coef.emm_list</code> , these are the ones we <i>exclude</i> .
row.names, optional	Required arguments of <code>as.data.frame</code> , ignored

Value

a list of objects returned by the corresponding `emmGrid` method (thus, often, another `emm_list` object). However, if `which` has length 1, the one result is not wrapped in a list.

`summary.emm_list` returns an object of class `summary_eml`, which is a list of `summary_emm` objects.

The `as.data.frame` methods return a single data frame via `as.data.frame(rbind(x))`. See also [rbind.emm_list](#) and [as.data.frame.emmGrid](#)

Note

The `plot` method uses only the first element of `which`; the others are ignored.

No `export` option is provided for printing an `emm_list` (see `print.emmGrid`). If you wish to export these objects, you must do so separately for each element in the list.

Examples

```
mod <- lm(conc ~ source, data = pigs)
obj <- emmeans(mod, pairwise ~ source)

linfct(obj)

coef(obj)      # done only for the contrasts

```

emm_options	<i>Set or change emmeans options</i>
-------------	--------------------------------------

Description

Use `emm_options` to set or change various options that are used in the **emmeans** package. These options are set separately for different contexts in which `emmGrid` objects are created, in a named list of option lists.

Usage

```
emm_options(..., disable)

get_emm_option(x, default = emm_defaults[[x]])

with_emm_options(..., expr)

emm_defaults
```

Arguments

<code>...</code>	Option names and values (see Details)
<code>disable</code>	If non-missing, this will reset all options to their defaults if <code>disable</code> tests TRUE (but first save them for possible later restoration). Otherwise, all previously saved options are restored. This is important for bug reporting; please see the section below on reproducible bugs. When <code>disable</code> is specified, the other arguments are ignored.
<code>x</code>	Character value - the name of an option to be queried
<code>default</code>	Value to return if <code>x</code> is not found
<code>expr</code>	Expression to evaluate. If missing, the last element of <code>...</code> is used.

Format

An object of class `list` of length 25.

Details

emmeans's options are stored as a list in the system option "emmeans". Thus, `emm_options(foo = bar)` is the same as `options(emmeans = list(..., foo = bar))` where ... represents any previously existing options. The list `emm_defaults` contains the default values in case the corresponding element of system option `emmeans` is `NULL`.

Currently, the following main list entries are supported:

`ref_grid` A named list of defaults for objects created by `ref_grid`. This could affect other objects as well. For example, if `emmeans` is called with a fitted model object, it calls `ref_grid` and this option will affect the resulting `emmGrid` object.

`emmeans` A named list of defaults for objects created by `emmeans` or `emtrends`.

`contrast` A named list of defaults for objects created by `contrast.emmGrid` or `pairs.emmGrid`.

`summary` A named list of defaults used by the methods `summary.emmGrid`, `predict.emmGrid`, `test.emmGrid`, `confint.emmGrid`, and `emmip`. The only option that can affect the latter four is "predict.type".

`allow.na.levs` A logical value that if `TRUE` (the default), allows `NA` to be among the levels of a factor. Older versions of **emmeans** did not allow this. So if problems come up (say in a messy dataset that includes incomplete cases), try setting this to `FALSE`.

`sep` A character value to use as a separator in labeling factor combinations. Such labels are potentially used in several places such as `contrast` and `plot.emmGrid` when combinations of factors are compared or plotted. The default is " ".

`parens` Character vector that determines which labels are parenthesized when they are contrasted. The first element is a regular expression, and the second and third elements are used as left and right parentheses. See details for the `parens` argument in `contrast`. The default will parenthesize labels containing the four arithmetic operators, using round parentheses.

`cov.keep` The default value of `cov.keep` in `ref_grid`. Defaults to "2", i.e., two-level covariates are treated like factors.

`graphics.engine` A character value matching `c("ggplot", "lattice")`, setting the default engine to use in `emmip` and `plot.emmGrid`. Defaults to "ggplot".

`gg.theme` An integer. Set it to 1 or 2 if you want the appearance of plots used in **emmeans** version 1.x.x or 2.x.x. Or set it to the actual theme that you want to use, e.g., `emm_options(gg.theme = ggplot2::theme_dark())`

`msg.interaction` A logical value controlling whether or not a message is displayed when `emmeans` averages over a factor involved in an interaction. It is probably not appropriate to do this, unless the interaction is weak. Defaults to `TRUE`.

`msg.nesting` A logical value controlling whether or not to display a message when a nesting structure is auto-detected. The existence of such a structure affects computations of EMMs. Sometimes, a nesting structure is falsely detected – namely when a user has omitted some main effects but included them in interactions. This does not change the model fit, but it produces a different parameterization that is picked up when the reference grid is constructed. Defaults to `TRUE`.

- `rg.limit` An integer value setting a limit on the number of rows in a newly constructed reference grid. This is checked based on the number of levels of the factors involved; but it excludes the levels of any multivariate responses because those are not yet known. The reference grid consists of all possible combinations of the predictors, and this can become huge if there are several factors. An error is thrown if this limit is exceeded. One can use the nuisance argument of `ref_grid` to collapse on nuisance factors, thus making the grid smaller. Defaults to 10,000.
- `simplify.names` A logical value controlling whether to simplify (when possible) names in the model formula that refer to datasets – for example, should we simplify a predictor name like “data\$trt” to just “trt”? Defaults to TRUE.
- `opt.digits` A logical value controlling the precision with which summaries are printed. If TRUE (default), the number of digits displayed is just enough to reasonably distinguish estimates from the ends of their confidence intervals; but always at least 3 digits. If FALSE, the system value `getOption("digits")` is used.
- `pval.digits` An integer indicating the precision with which p-values are printed. Integers between 2 and 6 are acceptable; the default is 4. Floating point numbers are truncated. If a number outside the accepted range is used, the nearest acceptable integer will be used instead. Non-numeric arguments are ignored.
- `back.bias.adj` A logical value controlling whether we try to adjust bias when back-transforming. If FALSE, we use naive back transformation. If TRUE *and sigma is available and valid*, a second-order adjustment is applied to estimate the mean on the response scale. A warning is issued if no valid sigma is available
- `enable.submodel` A logical value. If TRUE, enables support for selected model classes to implement the submodel option. If FALSE, this support is disabled. Setting this option to FALSE could save excess memory consumption.

Some other options have more specific purposes:

- `estble.tol` Tolerance for determining estimability in rank-deficient cases. If absent, the value in `emm_defaults$estble.tol` is used.
- `save.ref_grid` Logical value of TRUE if you wish the latest reference grid created to be saved in `.Last.ref_grid`. The default is FALSE.

Options for `lme4::lmerMod` models Options `lmer.df`, `disable.pbkrtest`, `pbkrtest.limit`, `disable.lmerTest`, and `lmerTest.limit` options affect how degrees of freedom are computed for `lmerMod` objects produced by the **lme4** package). See that section of the "models" vignette for details.

- `post.ci.method` method for estimating confidence intervals for Bayesian models. Options are "HPD" (default) or "quantile".

Value

`emm_options` returns the current options (same as the result of `'getOption("emmeans")'`) – invisibly, unless called with no arguments.

`get_emm_option` returns the currently stored option for `x`, or its default value if not found.

`with_emm_options()` temporarily sets the options in `...`, then evaluates `try(expr)` and returns the result.

Reproducible bugs

Most options set display attributes and such that are not likely to be associated with bugs in the code. However, some other options (e.g., `cov.keep`) are essentially configuration settings that may affect how/whether the code runs, and the settings for these options may cause subtle effects that may be hard to reproduce. Therefore, when sending a bug report, please create a reproducible example and make sure the bug occurs with all options set at their defaults. This is done by preceding it with `emm_options(disable = TRUE)`.

By the way, `disable` works like a stack (LIFO buffer), in that `disable = TRUE` is equivalent to `emm_options(saved.opts = emm_options())` and `emm_options(disable = FALSE)` is equivalent to `options(emmeans = get_emm_option("saved.opts"))`. To completely erase all options, use `options(emmeans = NULL)`

Startup options

`emmeans`'s options are kept in the system options in a list names `emmeans`. Thus, if the user wants certain options set on startup, this can be arranged by setting the `emmeans` option in one's startup script. For example, the user's `.Rprofile` file could contain:

```
options(emmeans = list(summary = list(predict.type = "response"),
                        lmer.df = "satterthwaite"))
```

## Not run:
emm_options(ref_grid = list(level = .90),
            contrast = list(infer = c(TRUE,FALSE)),
            estble.tol = 1e-6)
# Sets default confidence level to .90 for objects created by ref.grid
# AS WELL AS emmeans called with a model object (since it creates a
# reference grid). In addition, when we call 'contrast', 'pairs', etc.,
# confidence intervals rather than tests are displayed by default.

## End(Not run)

## Not run:
emm_options(disable.pbkrtest = TRUE)
# This forces use of asymptotic methods for lmerMod objects.
# Set to FALSE or NULL to re-enable using pbkrtest.

## End(Not run)

# See tolerance being used for determining estimability
get_emm_option("estble.tol")

## Not run:
# Set all options to their defaults
```

```

emm_options(disable = TRUE)
# ... and perhaps follow with code for a minimal reproducible bug,
#   which may include emm_options() calls if they are pertinent ...

# restore options that had existed previously
emm_options(disable = FALSE)

## End(Not run)

# Temporarily alter the formatting of labels in an interaction contrast:
pigs.lm <- lm(inverse(conc) ~ source * factor(percent), data = pigs)
with_emm_options(parens = c("\\-", "<", ">"), sep = ": ",
  contrast(contrast(ref_grid(pigs.lm), "consec", by = "percent"),
    "consec", by = NULL))

```

emrends

*Estimated marginal means of linear trends***Description**

The `emrends` function is useful when a fitted model involves a numerical predictor x interacting with another predictor a (typically a factor). Such models specify that x has a different trend depending on a ; thus, it may be of interest to estimate and compare those trends. Analogous to the [emmeans](#) setting, we construct a reference grid of these predicted trends, and then possibly average them over some of the predictors in the grid.

Usage

```
emrends(object, specs, var, delta.var = 0.001 * rng, max.degree = 1, ...)
```

Arguments

<code>object</code>	A supported model object (<i>not</i> a reference grid)
<code>specs</code>	Specifications for what marginal trends are desired – as in emmeans . If <code>specs</code> is missing or <code>NULL</code> , <code>emmeans</code> is not run and the reference grid for specified trends is returned.
<code>var</code>	Character value giving the name of a variable with respect to which a difference quotient of the linear predictors is computed. In order for this to be useful, <code>var</code> should be a numeric predictor that interacts with at least one factor in <code>specs</code> . Then instead of computing EMMs, we compute and compare the slopes of the <code>var</code> trend over levels of the specified other predictor(s). As in EMMs, marginal averages are computed for the predictors in <code>specs</code> and <code>by</code> . See also the “Generalizations” section below.
<code>delta.var</code>	The value of h to use in forming the difference quotient $(f(x + h) - f(x))/h$. Changing it (especially changing its sign) may be necessary to avoid numerical problems such as logs of negative numbers. The default value is 1/1000 of the range of <code>var</code> over the dataset.

<code>max.degree</code>	Integer value. The maximum degree of trends to compute (this is capped at 5). If greater than 1, an additional factor degree is added to the grid, with corresponding numerical derivatives of orders 1, 2, ..., <code>max.degree</code> as the estimates.
<code>...</code>	Additional arguments passed to <code>ref_grid</code> or <code>emmeans</code> as appropriate. See Details.

Details

The function works by constructing reference grids for `object` with various values of `var`, and then calculating difference quotients of predictions from those reference grids. Finally, `emmeans` is called with the given specs, thus computing marginal averages as needed of the difference quotients. Any `...` arguments are passed to the `ref_grid` and `emmeans`; examples of such optional arguments include optional arguments (often `mode`) that apply to specific models; `ref_grid` options such as `data`, `at`, `cov.reduce`, `mult.names`, `nesting`, or `transform`; and `emmeans` options such as `weights` (but please avoid `trend` or `offset`).

Value

An `emmGrid` or `emm_list` object, according to specs. See `emmeans` for more details on when a list is returned.

Generalizations

Instead of a single predictor, the user may specify some monotone function of one variable, e.g., `var = "log(dose)"`. If so, the chain rule is applied. Note that, in this example, if `object` contains `log(dose)` as a predictor, we will be comparing the slopes estimated by that model, whereas specifying `var = "dose"` would perform a transformation of those slopes, making the predicted trends vary depending on dose.

Note

In earlier versions of `emtrends`, the first argument was named `model` rather than `object`. (The name was changed because of potential mis-matching with a `mode` argument, which is an option for several types of models.) For backward compatibility, `model` still works *provided all arguments are named*.

It is important to understand that trends computed by `emtrends` are *not* equivalent to polynomial contrasts in a parallel model where `var` is regarded as a factor. That is because the model object here is assumed to fit a smooth function of `var`, and the estimated trends reflect *local* behavior at particular value(s) of `var`; whereas when `var` is modeled as a factor and polynomial contrasts are computed, those contrasts represent the *global* pattern of changes over *all* levels of `var`.

See the `pigs.poly` and `pigs.fact` examples below for an illustration. The linear and quadratic trends depend on the value of `percent`, but the cubic trend is constant (because that is true of a cubic polynomial, which is the underlying model). The cubic contrast in the factorial model has the same P value as for the cubic trend, again because the cubic trend is the same everywhere.

Examples

```

fiber.lm <- lm(strength ~ diameter*machine, data=fiber)
# Obtain slopes for each machine ...
( fiber.emt <- emtrends(fiber.lm, "machine", var = "diameter") )
# ... and pairwise comparisons thereof
pairs(fiber.emt)

# Suppose we want trends relative to sqrt(diameter)...
emtrends(fiber.lm, ~ machine | diameter, var = "sqrt(diameter)",
          at = list(diameter = c(20, 30)))

# Obtaining a reference grid
mtcars.lm <- lm(mpg ~ poly(disp, degree = 2) * (factor(cyl) + factor(am)), data = mtcars)

# Center trends at mean disp for each no. of cylinders
mtcTrends.rg <- emtrends(mtcars.lm, var = "disp",
                        cov.reduce = disp ~ factor(cyl))
summary(mtcTrends.rg) # estimated trends at grid nodes
emmeans(mtcTrends.rg, "am", weights = "prop")

### Higher-degree trends ...

pigs.poly <- lm(conc ~ poly(percent, degree = 3), data = pigs)
emt <- emtrends(pigs.poly, ~ degree | percent, "percent", max.degree = 3,
               at = list(percent = c(9, 13.5, 18)))
# note: 'degree' is an extra factor created by 'emtrends'

summary(emt, infer = c(TRUE, TRUE))

# Compare above results with poly contrasts when 'percent' is modeled as a factor ...
pigs.fact <- lm(conc ~ factor(percent), data = pigs)
emm <- emmeans(pigs.fact, "percent")

contrast(emm, "poly")
# Some P values are comparable, some aren't! See Note in documentation

```

Description

This documents some functions and methods that may be useful to package developers wishing to add support for **emmeans** for their model objects. A user or package developer may add **emmeans** support for a model class by writing `recover_data` and `emm_basis` methods for that class. (Users in need for a quick way to obtain results for a model that is not supported may be better served by the [qdr](#) function.) There are several other exported functions that may be useful. See the "xtending" vignette for more details.

Usage

```

recover_data(object, ...)

## S3 method for class 'call'
recover_data(object, trms, na.action, data = NULL,
  params = "pi", frame, pwts, addl.vars, ...)

emm_basis(object, trms, xlev, grid, ...)

.emm_register(classes, pkgname, qdrg = FALSE)

.std.link.labels(fam, misc)

.combine.terms(...)

.aovlist.dffun(k, dfargs)

.cmpMM(X, weights = rep(1, nrow(X)), assign = attr(X$qr, "assign"))

.get.excl(levs, exc, inc)

.get.offset(terms, grid)

.my.vcov(object, vcov. = .statsvcov, ...)

.all.vars(expr, retain = c("\\$", "\\[\\[", "\\]\\]", "'", "\""),
  ...)

.diag(x, nrow, ncol)

.num.key(levs, key)

.emm_vignette(css = system.file("css", "clean-simple.css", package =
  "emmeans"), highlight = NULL, ...)

.hurdle.support(cmu, cshape, cp0, cmean, zmu, zshape, zp0)

.zi.support(zmu, zshape, zp0)

```

Arguments

object	An object of the same class as is supported by a new method.
...	Additional parameters that may be supported by the method.
trms	The <code>terms</code> component of object (typically with the response deleted, e.g. via delete.response)
na.action	Integer vector of indices of observations to ignore; or NULL if none

data	Data frame. Usually, this is NULL. However, if non-null, this is used in place of the reconstructed dataset. It must have all of the predictors used in the model, and any factor levels must match those used in fitting the model.
params	Character vector giving the names of any variables in the model formula that are <i>not</i> predictors. For example, a spline model may involve a local variable knots that is not a predictor, but its value is needed to fit the model. Names of parameters not actually used are harmless, and the default value "pi" (the only numeric constant in base R) is provided in case the model involves it. An example involving splines may be found at https://github.com/rvlenth/emmeans/issues/180 .
frame	Optional data.frame. Many model objects contain the model frame used when fitting the model. In cases where there are no predictor transformations, this model frame has all the original predictor values and so is usable for recovering the data. Thus, if frame is non-missing and data is NULL, a check is made on trms and if there are no function calls, we use data = frame. This can be helpful because it provides a modicum of security against the possibility that the original data used when fitting the model has been altered or removed.
pwts	Optional vector of prior weights. Typically, this may be obtained from the fitted model via weights(model). If this is provided, it is used to set weights as long as it is non-NULL and the same length as the number of rows of the data.
addl.vars	Character value or vector specifying additional predictors to include in the reference grid. These must be names of variables that exist, or you will get an error. This may be useful if you need to do additional computations later on that depend on these variables; e.g., bias adjustments for random slopes of variables not among the fixed predictors.
xlev	Named list of factor levels (<i>excluding</i> ones coerced to factors in the model formula)
grid	A data.frame (provided by ref_grid) containing the predictor settings needed in the reference grid
classes	Character names of one or more classes to be registered. The package must contain the functions recover_data.foo and emm_basis.foo for each class foo listed in classes.
pkgrname	Character name of package providing the methods (usually should be the second argument of .onLoad)
qdrgr	Logical value. If FALSE, the recover_data and emm_basis methods are registered. If TRUE, the qdrgr method for each class is registered instead.
fam	Result of call to family(object)
misc	A list intended for the @misc slot of an emmGrid object
k, dfargs	Arguments to .aovlist.dffun, which is made available as a convenience to developers providing support similar to that provided for aovlist objects
X, weights, assign	Arguments for .cmpMM, which compacts a model matrix X into a much smaller matrix that has the same row space. Specifically, it returns the R portion of its QR decomposition. If X is already of class qr, it is used directly. weights should be the weights used in the model fit, and assign is used for unravelling any pivoting done by qr.

levs, key	The <code>.num.key</code> function returns the numeric indices of the levels in <code>levs</code> to the set of all levels in <code>key</code>
exc, inc	Arguments for <code>.get.excl</code> which is useful in writing <code>.emmc</code> functions for generating contrast coefficients, and supports arguments <code>exclude</code> or <code>include</code> for excluding or specifying which levels to use.
terms	A terms component
vcov.	Function or matrix that returns a suitable covariance matrix. The default is <code>.statsvcov</code> which is <code>stats::vcov</code> . The <code>.my.vcov</code> function should be called in place of <code>vcov</code> , and it supports the user being able to specify a different matrix or function via the optional <code>vcov.</code> argument.
expr, retain	Arguments for <code>.all.vars</code> , which is an alternative to <code>all.vars</code> that has special provisions for retaining the special characters in <code>retain</code> , thus allowing model specifications like <code>y ~ data\$trt * df[["dose"]]</code>
x, nrow, ncol	Arguments for <code>.diag</code> , which is an alternative to <code>diag</code> that lacks its idiosyncrasy of returning an identity matrix when <code>x</code> is of length 1.
css, package, highlight	Arguments for <code>.emm_vignette</code> , which is a clean and simple alternative to such as <code>html_document</code> for use as the output style of a Markdown file. All the vignettes in the emmeans package use this output style.
cmu, zmu	In <code>.hurdle.support</code> and <code>.zi.support</code> , these specify a vector of back-transformed estimates for the count and zero model, respectively
cshape, zshape	Shape parameter for the count and zero model, respectively
cp0, zp0	Function of <code>(mu, shape)</code> for computing $\text{Prob}(Y = 0)$ for the count and zero model, respectively
cmean	Function of <code>(mu, shape)</code> for computing the mean of the count model. Typically, this just returns <code>mu</code>

Value

The `recover_data` method must return a [data.frame](#) containing all the variables that appear as predictors in the model, and attributes `"call"`, `"terms"`, `"predictors"`, and `"responses"`. (`recover_data.call` will provide these attributes.)

The `emm_basis` method should return a list with the following elements:

X The matrix of linear functions over `grid`, having the same number of rows as `grid` and the number of columns equal to the length of `bhat`.

bhat The vector of regression coefficients for fixed effects. This should *include* any NAs that result from rank deficiencies.

nbasis A matrix whose columns form a basis for non-estimable functions of beta, or a 1x1 matrix of NA if there is no rank deficiency.

V The estimated covariance matrix of `bhat`.

dfun A function of `(k, dfargs)` that returns the degrees of freedom associated with `sum(k * bhat)`.

dfargs A list containing additional arguments needed for `dfun`.

`.std.link.llabels` returns a modified version of `misc` with the appropriate information included corresponding to the information in `fam`

`combine.terms` returns a `terms` object resulting from combining all the terms or formulas in

`.get.offset` returns the values, based on `grid`, of any offset component in `terms`

`.hurdle.support` returns a matrix with 3 rows containing the estimated mean responses and the differentials wrt `cmu` and `zmu`, resp.

`.zi.support` returns a matrix with 2 rows containing the estimated probabilities of 0 and the differentials wrt `mu`. See the section on hurdle and zero-inflated models.

Details

To create a reference grid, the `ref_grid` function needs to reconstruct the data used in fitting the model, and then obtain a matrix of linear functions of the regression coefficients for a given grid of predictor values. These tasks are performed by calls to `recover_data` and `emm_basis` respectively. A vignette giving details and examples is available via `vignette("xtending", "emmeans")`

To extend **emmeans**'s support to additional model types, one need only write S3 methods for these two functions. The existing methods serve as helpful guidance for writing new ones. Most of the work for `recover_data` can be done by its method for class `"call"`, providing the `terms` component and `na.action` data as additional arguments. Writing an `emm_basis` method is more involved, but the existing methods (e.g., `emmeans::emm_basis.lm`) can serve as models. Certain `recover_data` and `emm_basis` methods are exported from **emmeans**. (To find out, do `methods("recover_data")`.) If your object is based on another model-fitting object, it may be that all that is needed is to call one of these exported methods and perhaps make modifications to the results. Contact the developer if you need others of these exported.

If the model has a multivariate response, `bhat` needs to be "flattened" into a single vector, and `X` and `V` must be constructed consistently.

In models where a non-full-rank result is possible (often, you can tell by seeing if there is a `singular.ok` argument in the model-fitting function), `summary.emmGrid` and its relatives check the estimability of each prediction, using the `nonest.basis` function in the **estimability** package.

The models already supported are detailed in the **"models"** vignette. Some packages may provide additional **emmeans** support for its object classes.

Communication between methods

If the `recover_data` method generates information needed by `emm_basis`, that information may be incorporated by creating a `"misc"` attribute in the returned recovered data. That information is then passed as the `misc` argument when `ref_grid` calls `emm_basis`.

Optional hooks

Some models may need something other than standard linear estimates and standard errors. If so, custom functions may be pointed to via the items `misc$estHook`, `misc$vcovHook` and `misc$postGridHook`. If just the name of the hook function is provided as a character string, then it is retrieved using `get`.

The `estHook` function should have arguments `'(object, do.se, tol, ...)'` where `object` is the `emmGrid` object, `do.se` is a logical flag for whether to return the standard error, and `tol` is the

tolerance for assessing estimability. It should return a matrix with 3 columns: the estimates, standard errors (NA when `do.se==FALSE`), and degrees of freedom (NA for asymptotic). The number of rows should equal `nrow(linfct(object))`. The `vcovHook` function should have arguments `(object, tol, ...)` as described. It should return the covariance matrix for the estimates. Finally, `postGridHook`, if present, is called at the very end of `ref_grid`; it takes one argument, the constructed object, and should return a suitably modified `emmGrid` object.

Registering S3 methods for a model class

The `.emm_register` function is provided as a convenience to conditionally register your S3 methods for a model class, `recover_data.foo` and `emm_basis.foo`, where `foo` is the class name. Your package should implement an `.onLoad` function and call `.emm_register` if **emmeans** is installed. See the example.

Support for Hurdle and Zero-inflated models

The functions `.hurdle.support` and `.zi.support` help facilitate calculations needed to estimate the mean response (count model and zero model combined) of these models. `.hurdle.support` returns a matrix of three rows. The first is the estimated mean for a hurdle model, and the 2nd and 3rd rows are differentials for the count and zero models, which needed for delta-method calculations. To use these, regard the `@linfct` slot as comprising two sets of columns, for the count and zero models respectively. To do the delta method calculations, multiply the rows of the count part by its differentials times `link$mu.eta` evaluated at that part of the linear predictor. Do the same for the zero part, using its differentials and `mu.eta`. If the resulting matrix is **A**, then the covariance of the mean response is **AVA'** where **V** is the `@V` slot of the object.

The function `zi.support` works the same way, only it is much simpler, and is used to estimate the probability of 0 and its differential for either part of a zero-inflated model or hurdle model.

See the code for `emm_basis.zeroinfl` and `emm_basis.hurdle` for how these are used with models fitted by the **pscl** package.

Note

Without an explicit data argument, `recover_data` returns the *current version* of the dataset. If the dataset has changed since the model was fitted, then this will not be the data used to fit the model. It is especially important to know this in simulation studies where the data are randomly generated or permuted, and in cases where several datasets are processed in one step (e.g., using `dplyr`). In those cases, users should be careful to provide the actual data used to fit the model in the data argument.

feedlot	<i>Feedlot data</i>
---------	---------------------

Description

This is an unbalanced analysis-of-covariance example, where one covariate is affected by a factor. Feeder calves from various herds enter a feedlot, where they are fed one of three diets. The weight of the animal at entry is the covariate, and the weight at slaughter is the response.

Usage

```
feedlot
```

Format

A data frame with 67 observations and 4 variables:

herd a factor with levels 9 16 3 32 24 31 19 36 34 35 33, designating the herd that a feeder calf came from.

diet a factor with levels Low Medium High: the energy level of the diet given the animal.

swt a numeric vector: the weight of the animal at slaughter.

ewt a numeric vector: the weight of the animal at entry to the feedlot.

Details

The data arise from a Western Regional Research Project conducted at New Mexico State University. Calves born in 1975 in commercial herds entered a feedlot as yearlings. Both diets and herds are of interest as factors. The covariate, ewt, is thought to be dependent on herd due to different genetic backgrounds, breeding history, etc. The levels of herd ordered to similarity of genetic background.

Note: There are some empty cells in the cross-classification of herd and diet.

Source

Urquhart NS (1982) Adjustment in covariates when one factor affects the covariate. *Biometrics* 38, 651-660.

Examples

```

feedlot.lm <- lm(swt ~ ewt + herd*diet, data = feedlot)

# Obtain EMMs with a separate reference value of ewt for each
# herd. This reproduces the last part of Table 2 in the reference
emmmeans(feedlot.lm, ~ diet | herd, cov.reduce = ewt ~ herd)

```

fiber

Fiber data

Description

Fiber data from Montgomery Design (8th ed.), p.656 (Table 15.10). Useful as a simple analysis-of-covariance example.

Usage

fiber

Format

A data frame with 15 observations and 3 variables:

machine a factor with levels A B C. This is the primary factor of interest.

strength a numeric vector. The response variable.

diameter a numeric vector. A covariate.

Details

The goal of the experiment is to compare the mean breaking strength of fibers produced by the three machines. When testing this, the technician also measured the diameter of each fiber, and this measurement may be used as a concomitant variable to improve precision of the estimates.

Source

Montgomery, D. C. (2013) *Design and Analysis of Experiments* (8th ed.). John Wiley and Sons, ISBN 978-1-118-14692-7.

Examples

```
fiber.lm <- lm(strength ~ diameter + machine, data=fiber)
ref_grid(fiber.lm)
```

```
# Covariate-adjusted means and comparisons
emmeans(fiber.lm, pairwise ~ machine)
```

hpd.summary	<i>Summarize an emmGrid from a Bayesian model</i>
-------------	---

Description

This function computes point estimates and HPD (or quantile) intervals for each factor combination in `object@emmGrid`. While this function may be called independently, it is called automatically by the S3 method `summary.emmGrid` when the object is based on a Bayesian model. (Note: the `level` argument, or its default, is passed as `prob`).

Usage

```
hpd.summary(object, prob, by, type, point.est = median,
  ci.method = get_emm_option("post.ci.method"), delta,
  bias.adjust = get_emm_option("back.bias.adj"), sigma, ...)
```

Arguments

<code>object</code>	an <code>emmGrid</code> object having a non-missing <code>post.beta</code> slot
<code>prob</code>	numeric probability content for HPD intervals (note: when not specified, the current <code>level</code> option is used; see emm_options)
<code>by</code>	factors to use as by variables
<code>type</code>	prediction type as in summary.emmGrid
<code>point.est</code>	function to use to compute the point estimates from the posterior sample for each grid point
<code>ci.method</code>	character value matching "HPD" (default) or "quantile" (but actually not case-sensitive). The default is to use HPD intervals (which are the shortest possible intervals). Alternatively, choosing "quantile" uses the quantiles of the posterior having equal tail probabilities.
<code>delta</code>	Numeric equivalence threshold (on the linear predictor scale regardless of type). See the section below on equivalence testing.
<code>bias.adjust</code>	Logical value for whether to adjust for bias in back-transforming (<code>type = "response"</code>). This requires a value of <code>sigma</code> to exist in the object or be specified.
<code>sigma</code>	Error SD assumed for bias correction (when <code>type = "response"</code>). If not specified, <code>object@misc\$sigma</code> is used, and a warning if it is not found or invalid. <i>Note:</i> <code>sigma</code> may be a vector, as long as it conforms to the number of observations in the posterior sample.
<code>...</code>	required but not used

Value

an object of class `summary_emm`

Equivalence testing note

If `delta` is positive, two columns labeled `p.equiv` and `odds.eq` are appended to the summary. `p.equiv` is the fraction of posterior estimates having absolute values less than `delta`. The `odds.eq` column is just `p.equiv` converted to an odds ratio; so it is the posterior odds of equivalence.

A high value of `p.equiv` is evidence in favor of equivalence. It can be used to obtain something equivalent (in spirit) to the frequentist Schuirmann (TOST) procedure, whereby we would conclude equivalence at significance level α if the $(1 - 2\alpha)$ confidence interval falls entirely in the interval $[-\delta, \delta]$. Similarly in the Bayesian context, an equally strong argument for equivalence is obtained if `p.equiv` exceeds $1 - 2\alpha$.

A closely related quantity is the ROPE (region of practical equivalence), obtainable via `bayestestR::rope(object, range = c(-delta, delta))`. Its value is approximately $100 * p.equiv / 0.95$ if the default `ci = 0.95` is used. See also **bayestestR's issue #567**.

Finally, a Bayes factor for equivalence is obtainable by dividing `odds.eq` by the prior odds of equivalence, assessed or elicited separately.

Note

HPD intervals require the **coda** package to be installed on your system; otherwise an error is thrown. (So one way to sidestep that error is to specify `ci.method = "quantile"`).

  # Use emm_example("hpd.summary-coda", list = TRUE) # to see just the code
```

joint_tests

Compute joint tests of the terms in a model

Description

This function produces an analysis-of-variance-like table based on linear functions of predictors in a model or `emmGrid` object. Specifically, the function constructs, for each combination of factors (or covariates reduced to two or more levels), a set of (interaction) contrasts via `contrast`, and then tests them using `test` with `joint = TRUE`. Optionally, one or more of the predictors may be used as by variable(s), so that separate tables of tests are produced for each combination of them.

Usage

```
joint_tests(object, by = NULL, show0df = FALSE, showconf = TRUE,
  cov.reduce = make.meanint(1), ...)
```

```
make.meanint(delta = 1, npts = 2)
```

```
meanint(x)
```

```
make.symmint(ctr, delta = 1, npts = 2)
```

```
symmint(ctr)
```

Arguments

object	a fitted model, emmGrid, or emm_list. If the latter, its first element is used.
by	character names of by variables. Separate sets of tests are run for each combination of these.
show0df	logical value; if TRUE, results with zero numerator degrees of freedom are displayed, if FALSE they are skipped
showconf	logical value. When we have models with estimability issues (e.g., missing cells), then with showconf = TRUE, we test any remaining effects that are not purely due to contrasts of a single term. If found, they are labeled (confounded). See vignette("xplanations") for more information.
cov.reduce	a function. If object is a fitted model, it is replaced by ref_grid(object, cov.reduce = cov.reduce, ...). For this purpose, the functions meanint and symmint are available for returning an interval around the mean or around zero, respectively. See the section below on covariates.
...	additional arguments passed to ref_grid and emmeans
delta, ctr	arguments for make.meanint and make.symmint. delta sets the distance each side of the center, so that the width of the interval is 2*delta.
npts	number of points to include in the interval
x	argument for meanint and symmint

Details

In models with only factors, no covariates, these tests correspond to “type III” tests a la **SAS**, as long as equal-weighted averaging is used and there are no estimability issues. When covariates are present and they interact with factors, the results depend on how the covariate is handled in constructing the reference grid. See the section on covariates below. The point that one must always remember is that `joint_tests` always tests contrasts among EMMs, in the context of the reference grid, whereas SAS’s type III tests are tests of model coefficients – which may or may not have anything to do with EMMs or contrasts.

Value

a `summary_emm` object (same as is produced by `summary.emmGrid`). All effects for which there are no estimable contrasts are omitted from the results. There may be an additional row named

(confounded) which accounts for additional degrees of freedom for effects not accounted for in the preceding rows.

The returned object also includes an "est.fcns" attribute, which is a named list containing the linear functions associated with each joint test. Each row of these is standardized to have length 1. No estimable functions are included for confounded effects.

make.meanint returns the function $\text{function}(x) \text{ mean}(x) + \text{delta} * c(-1, 1)$, and make.symmint(ctr, delta) returns the function $\text{function}(x) \text{ ctr} + \text{delta} * c(-1, 1)$ (which does not depend on x). The cases with $\text{delta} = 1$, $\text{meanint} = \text{make.meanint}(1)$ and $\text{symmint}(\text{ctr}) = \text{make.symmint}(\text{ctr}, 1)$ are retained for back-compatibility reasons. These functions are available primarily for use with cov.reduce.

Dealing with covariates

A covariate (or any other predictor) must have *more than one value in the reference grid* in order to test its effect and be included in the results. Therefore, when object is a model, we default to `cov.reduce = meanint` which sets each covariate at a symmetric interval about its mean. But when object is an existing reference grid, it often has only one value for covariates, in which case they are excluded from the joint tests.

While having two points is sufficient when the covariate term has a linear trend, you need more than two when some kind of curved trend (polynomial, spline, etc.) is present – else `joint_tests()` will not show enough degrees of freedom for terms involving the covariate. You may specify these points manually using `at`, or by including an `npts` argument in `cov.reduce`, via `make.meanint` or `make.symmint()`. With some kinds of curved trends, the joint tests of covariate terms may become somewhat meaningless.

Covariates present further complications in that their values in the reference grid can affect the joint tests of *other* effects. When covariates are centered around their means (the default), then the tests we obtain can be described as joint tests of covariate-adjusted means; and that is our intended use here. However, some software such as **SAS** and `car::Anova` adopt the convention of centering covariates around zero; and for that purpose, one can use `cov.reduce = symmint(0)` when calling with a model object (or in constructing a reference grid). However, adjusted means with covariates set at or around zero do not make much sense in the context of interpreting estimated marginal means, unless the covariate means really are zero.

See the examples below with the toy dataset.

Note

`joint_tests` is flaky with models having nested fixed effects. In some cases, terms that could be relevant are not identified, or confounded with unidentifiable terms.

[test](#)

Examples

```
pigs.lm <- lm(log(conc) ~ source * factor(percent), data = pigs)
(jt <- joint_tests(pigs.lm))           ## will be same as type III ANOVA
```

```

### Estimable functions associated with "percent"
attr(jt, "est.fcns") $ "percent"

joint_tests(pigs.lm, weights = "outer") ## differently weighted

joint_tests(pigs.lm, by = "source")      ## separate joint tests of 'percent'

### Comparisons with type III tests in SAS
toy = data.frame(
  treat = rep(c("A", "B"), c(4, 6)),
  female = c(1, 0, 0, 1, 0, 0, 0, 1, 1, 0),
  resp = c(17, 12, 14, 19, 28, 26, 26, 34, 33, 27))
toy.fac = lm(resp ~ treat * factor(female), data = toy)
toy.cov = lm(resp ~ treat * female, data = toy)
# (These two models have identical fitted values and residuals)

# -- SAS output we'd get with toy.fac --
## Source      DF    Type III SS    Mean Square    F Value    Pr > F
## treat       1    488.8928571    488.8928571    404.60    <.0001
## female      1     78.8928571     78.8928571     65.29    0.0002
## treat*female 1     1.7500000     1.7500000     1.45    0.2741
#
# -- SAS output we'd get with toy.cov --
## Source      DF    Type III SS    Mean Square    F Value    Pr > F
## treat       1    252.0833333    252.0833333    208.62    <.0001
## female      1     78.8928571     78.8928571     65.29    0.0002
## female*treat 1     1.7500000     1.7500000     1.45    0.2741

joint_tests(toy.fac)
joint_tests(toy.cov) # female is regarded as a 2-level factor by default

## Treat 'female' as a numeric covariate (via cov.keep = 0)
## ... then tests depend on where we center things

# Center around the mean
joint_tests(toy.cov, cov.keep = 0, cov.reduce = make.meanint(delta = 1))
# Center around zero (like SAS's results for toy.cov)
joint_tests(toy.cov, cov.keep = 0, cov.reduce = make.symmint(ctr = 0, delta = 1))
# Center around 0.5 (like SAS's results for toy.fac)
joint_tests(toy.cov, cov.keep = 0, cov.reduce = range)

### Example with empty cells and confounded effects
low3 <- unlist(attr(ubds, "cells")[1:3])
ubds.lm <- lm(y ~ A*B*C, data = ubds, subset = -low3)

# Show overall joint tests by C:
ref_grid(ubds.lm, by = "C") |> contrast("consec") |> test(joint = TRUE)

# Break each of the above into smaller components:
joint_tests(ubds.lm, by = "C")

```

 lsmeans

Wrappers for alternative naming of EMMs

Description

These are wrappers for [emmeans](#) and related functions to provide backward compatibility, or for users who may prefer to use other terminology than “estimated marginal means” – namely “least-squares means”. These functions also provide the functionality formerly provided by the **lsmeans** package, which is now just a front-end for **emmeans**.

Usage

```
lsmeans(...)
lstrends(...)
lsmip(...)
lsm(...)
lsmobj(...)
lsm.options(...)
get.lsm.option(x, default = emm_defaults[[x]])
```

Arguments

...	Arguments passed to the corresponding <code>emxxx</code> function
x	Character name of desired option
default	default value to return if x not found

Details

For each function with `lsxxx` in its name, the same function named `emxxx` is called. Any estimator names or list items beginning with “em” are replaced with “ls” before the results are returned

Value

The result of the call to `emxxx`, suitably modified.

`get.lsm.option` and `lsm.options` remap options from and to corresponding options in the **emmeans** options system.

See Also

[emmeans](#), [emtrends](#), [emmip](#), [emm](#), [emmobj](#), [emm_options](#), [get_emm_option](#)

Examples

```
pigs.lm <- lm(log(conc) ~ source + factor(percent), data = pigs)
lsmeans(pigs.lm, "source")
```

make.tran

Response-transformation extensions

Description

The `make.tran` function creates the needed information to perform transformations of the response variable, including inverting the transformation and estimating variances of back-transformed predictions via the delta method. `make.tran` is similar to `make.link`, but it covers additional transformations. The result can be used as an environment in which the model is fitted, or as the `tran` argument in `update.emmGrid` (when the given transformation was already applied in an existing model).

Usage

```
make.tran(type = c("genlog", "power", "boxcox", "sympower", "asin.sqrt",
  "atanh", "bcnPower", "scale"), alpha = 1, beta = 0, param, y, inner, ...)

inverse(y)
```

Arguments

<code>type</code>	The name of a standard transformation supported by <code>stat::make.link</code> , or of a special transformation described under <i>Details</i> .
<code>alpha, beta</code>	Numeric parameters needed for special transformations.
<code>param</code>	If non-missing, this specifies either <code>alpha</code> or <code>c(alpha, beta)</code> (provided for backward compatibility). Also, for the same reason, if <code>alpha</code> is of length more than 1, it is taken as <code>param</code> .
<code>y</code>	A numeric response variable used (<i>and required</i>) with <code>type = "scale"</code> , where <code>scale(y)</code> determines <code>alpha</code> and <code>beta</code> .
<code>inner</code>	another transformation. See the section on compound transformations
<code>...</code>	Additional arguments passed to other functions/methods

Value

A list having at least the same elements as those returned by `make.link`. The `linkfun` component is the transformation itself. Each of the functions is associated with an environment where any parameter values are defined.

`inverse` returns the reciprocal of its argument. It allows the "inverse" link to be auto-detected as a response transformation.

Details

The `make.tran` function returns a suitable list of functions for several popular transformations. Besides being usable with `update`, the user may use this list as an enclosing environment in fitting the model itself, in which case the transformation is auto-detected when the special name `linkfun` (the transformation itself) is used as the response transformation in the call. See the examples below.

The primary purpose of `make.tran` is to support transformations that require additional parameters, specified as `alpha` and `beta`; these are the ones shown in the argument-matching list. However, standard transformations supported by `stats::make.link` are also supported. In the following discussion of ones requiring parameters, we use α and β to denote alpha and beta, and y to denote the response variable. The `type` argument specifies the following transformations:

"genlog" Generalized logarithmic transformation: $\log_{\beta}(y + \alpha)$, where $y > -\alpha$. When $\beta = 0$ (the default), we use $\log_e(y + \alpha)$

"power" Power transformation: $(y - \beta)^{\alpha}$, where $y > \beta$. When $\alpha = 0$, $\log(y - \beta)$ is used instead.

"boxcox" The Box-Cox transformation (unscaled by the geometric mean): $((y - \beta)^{\alpha} - 1)/\alpha$, where $y > \beta$. When $\alpha = 0$, $\log(y - \beta)$ is used.

"sympower" A symmetrized power transformation on the whole real line: $|y - \beta|^{\alpha} \cdot \text{sign}(y - \beta)$. There are no restrictions on y , but we require $\alpha > 0$ in order for the transformation to be monotone and continuous.

"asin.sqrt" Arcsin-square-root transformation: $\sin^{-1}(y/\alpha)^{1/2}$. Typically, alpha will be either 1 (default) or 100.

"atanh" Arctanh transformation: $\tanh^{-1}(y/\alpha)$. Typically, alpha will be either 1 (default) or 100.

"bcnPower" Box-Cox with negatives allowed, as described for the `bcnPower` function in the `car` package. It is defined as the Box-Cox transformation $(z^{\alpha} - 1)/\alpha$ of the variable $z = y + (y^2 + \beta^2)^{1/2}$. Note that this requires both parameters and that $\beta > 0$.

"scale" This one is a little different than the others, in that alpha and beta are ignored; instead, they are determined by calling `scale(y, ...)`. The user should give as `y` the response variable in the model to be fitted to its scaled version.

Note that with the "power", "boxcox", or "sympower" transformations, the argument `beta` specifies a location shift. In the "genpower" transformation, `beta` specifies the base of the logarithm – however, quirkily, the default of `beta = 0` is taken to be the natural logarithm. For example, `make.tran(0.5, 10)` sets up the $\log_{10}(y + \frac{1}{2})$ transformation. In the "bcnPower" transformation, `beta` must be specified as a positive value.

For purposes of back-transformation, the '`sqrt(y) + sqrt(y+1)`' transformation is treated exactly the same way as '`2*sqrt(y)`', because both are regarded as estimates of $2\sqrt{\mu}$.

Cases where `make.tran` may not be needed

For standard transformations with no parameters, we usually don't need to use `make.tran`; just the name of the transformation is all that is needed. The functions `emmeans`, `ref_grid`, and related ones automatically detect response transformations that are recognized by examining the model formula. These are `log`, `log2`, `log10`, `log1p`, `sqrt`, `logit`, `probit`, `cauchit`, `cloglog`; as well as (for a response variable `y`) `asin(sqrt(y))`, `asinh(sqrt(y))`, `atanh(y)`, and `sqrt(y) + sqrt(y+1)`. In addition, any constant multiple of these (e.g., `2*sqrt(y)`) is auto-detected and appropriately scaled (see also the `tran.mult` argument in `update.emmGrid`).

A few additional transformations may be specified as character strings and are auto-detected: "identity", "1/mu^2", "inverse", "reciprocal", "log10", "log2", "asin.sqrt", "asinh.sqrt", and "atanh".

Compound transformations

A transformation that is a function of another function can be created by specifying `inner` for the other function. For example, the transformation $1/\sqrt{y}$ can be created either by `make.tran("inverse", inner = "sqrt")` or by `make.tran("power", -0.5)`. In principle, transformations can be compounded to any depth. Also, if `type` is "scale", `y` is replaced by `inner$linkfun(y)`, because that will be the variable that is scaled.

Note

The `genlog` transformation is technically unneeded, because a response transformation of the form $\log(y + c)$ is now auto-detected by `ref_grid`.

We modify certain `make.link` results in transformations where there is a restriction on valid prediction values, so that reasonable inverse predictions are obtained, no matter what. For example, if a `sqrt` transformation was used but a predicted value is negative, the inverse transformation is zero rather than the square of the prediction. A side effect of this is that it is possible for one or both confidence limits, or even a standard error, to be zero.

Examples

```
# Fit a model using an oddball transformation:
bctran <- make.tran("boxcox", 0.368)
warp.bc <- with(bctran,
  lm(linkfun(breaks) ~ wool * tension, data = warpbreaks))
# Obtain back-transformed LS means:
emmeans(warp.bc, ~ tension | wool, type = "response")

### Using a scaled response...
# Case where it is auto-detected:
mod <- lm(scale(yield[, 1]) ~ Variety, data = MOats)
emmeans(mod, "Variety", type = "response")

# Case where scaling is not auto-detected -- and what to do about it:
copt <- options(contrasts = c("contr.sum", "contr.poly"))
mod.aov <- aov(scale(yield[, 1]) ~ Variety + Error(Block), data = MOats)
emm.aov <- suppressWarnings(emmeans(mod.aov, "Variety", type = "response"))

# Scaling was not retrieved, but we can do:
emm.aov <- update(emm.aov, tran = make.tran("scale", y = MOats$yield[, 1]))
emmeans(emm.aov, "Variety", type = "response")

### Compound transformations
# The following amount to the same thing:
t1 <- make.tran("inverse", inner = "sqrt")
t2 <- make.tran("power", -0.5)

options(copt)
```

```
## Not run:
### An existing model 'mod' was fitted with a y^(2/3) transformation...
  ptran = make.tran("power", 2/3)
  emmeans(mod, "treatment", tran = ptran)

## End(Not run)

pigs.lm <- lm(inverse(conc) ~ source + factor(percent), data = pigs)
emmeans(pigs.lm, "source", type = "response")
```

MOats

Oats data in multivariate form

Description

This is the Oats dataset provided in the **nlme** package, but it is rearranged as one multivariate observation per plot.

Usage

MOats

Format

A data frame with 18 observations and 3 variables

Variety a factor with levels Golden Rain, Marvellous, Victory

Block an ordered factor with levels VI < V < III < IV < II < I

yield a matrix with 4 columns, giving the yields with nitrogen concentrations of 0, .2, .4, and .6.

Details

These data arise from a split-plot experiment reported by Yates (1935) and used as an example in Pinheiro and Bates (2000) and other texts. Six blocks were divided into three whole plots, randomly assigned to the three varieties of oats. The whole plots were each divided into 4 split plots and randomized to the four concentrations of nitrogen.

Source

The dataset [Oats](#) in the **nlme** package.

References

Yates, F. (1935) Complex experiments, *Journal of the Royal Statistical Society* Suppl. 2, 181-247

Examples

```
MOats.lm <- lm (yield ~ Block + Variety, data = MOats)
MOats.rg <- ref_grid (MOats.lm, mult.name = "nitro")
emmeans(MOats.rg, ~ nitro | Variety)
```

models	<i>Models supported in emmeans</i>
--------	------------------------------------

Description

Documentation for models has been moved to a vignette. To access it, use `vignette("models", "emmeans")`.

mvcontrast	<i>Multivariate contrasts</i>
------------	-------------------------------

Description

This function displays tests of multivariate comparisons or contrasts. The contrasts are constructed at each level of the variable in `mult.name`, and then we do a multivariate test that the vector of estimates is equal to null (zero by default). The F statistic and degrees of freedom are determined via the Hotelling distribution. that is, if there are m error degrees of freedom and multivariate dimensionality d , then the resulting F statistic has degrees of freedom $(d, m - d + 1)$ as shown in Hotelling (1931).

Usage

```
mvcontrast(object, method = "eff", mult.name = object@roles$multresp,
  null = 0, by = object@misc$by.vars, adjust = c("sidak",
  p.adjust.methods), show.ests = FALSE, ...)
```

Arguments

object	An object of class <code>emmGrid</code>
method	A contrast method, per contrast.emmGrid
mult.name	Character vector of names of the factors whose levels define the multivariate means to contrast. If the model itself has a multivariate response, that is what is used. Otherwise, <code>mult.name</code> <i>must</i> be specified.
null	Scalar or conformable vector of null-hypothesis values to test against
by	Any by variable(s). These should not include the primary variables to be contrasted. For convenience, the by variable is nulled-out if it would result in no primary factors being contrasted.
adjust	Character value of a multiplicity adjustment method ("none" for no adjustment). The available adjustment methods are more limited than in <code>contrast</code> , and any default adjustment returned via <code>method</code> is ignored.
show.ests	Logical flag determining whether the multivariate means are displayed
...	Additional arguments passed to <code>contrast</code>

Value

An object of class `summary_emm` containing the multivariate test results; or a list of the estimates and the tests if `show.ests` is `TRUE`. The test results include the Hotelling T^2 statistic, F ratios, degrees of freedom, and P values.

Note

If some interactions among the primary and `mult.name` factors are absent, the covariance of the multivariate means is singular; this situation is accommodated, but the result has reduced degrees of freedom and a message is displayed. If there are other abnormal conditions such as non-estimable results, estimates are shown as NA.

While designed primarily for testing contrasts, multivariate tests of the mean vector itself can be implemented via `method = "identity"` (see the examples).

References

Hotelling, Harold (1931) "The generalization of Student's ratio", *Annals of Mathematical Statistics* 2(3), 360–378. doi:10.1214/aoms/1177732979

Examples

```
MOats.lm <- lm(yield ~ Variety + Block, data = MOats)
MOats.emm <- emmeans(MOats.lm, ~ Variety | rep.meas)
mvcontrast(MOats.emm, "consec", show.ests = TRUE) # mult.name defaults to rep.meas

# Test each mean against a specified null vector
mvcontrast(MOats.emm, "identity", name = "Variety",
           null = c(80, 100, 120, 140), adjust = "none")
# (Note 'name' is passed to contrast() and overrides default name "contrast")

# 'mult.name' need not refer to a multivariate response
mvcontrast(MOats.emm, "trt.vs.ctr11", mult.name = "Variety")
```

mvregrid

Multivariate regridding

Description

This function is similar to `regrid` except it performs a multivariate transformation. This is useful, for instance, in multivariate models that have a compositional response.

Usage

```
mvregrid(object, newname = "component", newlevs = seq_len(ncol(newy)),
         mult.name = names(levels)[length(levels)], fcn = paste0(tran, "Inv"),
         ...)
```

Arguments

object	An emmGrid object
newname	The name to give to the newly created multivariate factor
newlevs	Character levels of the newly created factor (must conform to the number of columns created by fcn)
mult.name	The name of the multivariate factor to be transformed. By default, we use the last factor
fcn	The multivariate function to apply. If character, we look for it in the namespace of the compositions package.
...	Additional arguments passed to fcn

Details

If a multivariate response transformation was used in fitting the model, its name is auto-detected, and in that case we need not specify fcn as long as its inverse can be found in the namespace of the **compositions** package. (That package need not be installed unless fcn is a character value.) For some such models, auto-detection process throws a warning message, especially if cbind is also present in the model formula.

Currently, no bias-adjustment option is available.

Value

A new emmGrid object with the newly created factor as its last factor

Examples

```
if(requireNamespace("compositions"))
  emm_example("mvregrid")
  # Use emm_example("mvregrid", list = TRUE) # to see just the code
```

neuralgia

Neuralgia data

Description

These data arise from a study of analgesic effects of treatments of elderly patients who have neuralgia. Two treatments and a placebo are compared. The response variable is whether the patient reported pain or not. Researchers recorded the age and gender of 60 patients along with the duration of complaint before the treatment began.

Usage

neuralgia

Format

A data frame with 60 observations and 5 variables:

Treatment Factor with 3 levels A, B, and P. The latter is placebo

Sex Factor with two levels F and M

Age Numeric covariate – patient’s age in years

Duration Numeric covariate – duration of the condition before beginning treatment

Pain Binary response factor with levels No and Yes

Source

Cai, Weijie (2014) *Making Comparisons Fair: How LS-Means Unify the Analysis of Linear Models*, SAS Institute, Inc. Technical paper 142-2014, page 12, <http://support.sas.com/resources/papers/proceedings14/SAS060-2014.pdf>

Examples

```
# Model and analysis shown in the SAS report:
neuralgia.glm <- glm(Pain ~ Treatment * Sex + Age, family = binomial(),
  data = neuralgia)
pairs(emmeans(neuralgia.glm, ~ Treatment, at = list(Sex = "F")),
  reverse = TRUE, type = "response", adjust = "bonferroni")
```

nutrition

Nutrition data

Description

This observational dataset involves three factors, but where several factor combinations are missing. It is used as a case study in Milliken and Johnson, Chapter 17, p.202. (You may also find it in the second edition, p.278.)

Usage

nutrition

Format

A data frame with 107 observations and 4 variables:

age a factor with levels 1, 2, 3, 4. Mother’s age group.

group a factor with levels FoodStamps, NoAid. Whether or not the family receives food stamp assistance.

race a factor with levels Black, Hispanic, White. Mother’s race.

gain a numeric vector (the response variable). Gain score (posttest minus pretest) on knowledge of nutrition.

Details

A survey was conducted by home economists “to study how much lower-socioeconomic-level mothers knew about nutrition and to judge the effect of a training program designed to increase their knowledge of nutrition.” This is a messy dataset with several empty cells.

Source

Milliken, G. A. and Johnson, D. E. (1984) *Analysis of Messy Data – Volume I: Designed Experiments*. Van Nostrand, ISBN 0-534-02713-7.

Examples

```
nutr.aov <- aov(gain ~ (group + age + race)^2, data = nutrition)

# Summarize predictions for age group 3
nutr.emm <- emmeans(nutr.aov, ~ race * group, at = list(age="3"))

emmip(nutr.emm, race ~ group)

# Hispanics seem exceptional; but this doesn't test out due to very sparse data
pairs(nutr.emm, by = "group")
pairs(nutr.emm, by = "race")
```

oranges

Sales of oranges

Description

This example dataset on sales of oranges has two factors, two covariates, and two responses. There is one observation per factor combination.

Usage

```
oranges
```

Format

A data frame with 36 observations and 6 variables:

store a factor with levels 1 2 3 4 5 6. The store that was observed.

day a factor with levels 1 2 3 4 5 6. The day the observation was taken (same for each store).

price1 a numeric vector. Price of variety 1.

price2 a numeric vector. Price of variety 2.

sales1 a numeric vector. Sales (per customer) of variety 1.

sales2 a numeric vector. Sales (per customer) of variety 2.

Source

This is (or once was) available as a SAS sample dataset.

References

Littell, R., Stroup W., Freund, R. (2002) *SAS For Linear Models* (4th edition). SAS Institute. ISBN 1-59047-023-0.

Examples

```
# Example on p.244 of Littell et al.
oranges.lm <- lm(sales1 ~ price1*day, data = oranges)
emmeans(oranges.lm, "day")

# Example on p.246 of Littell et al.
emmeans(oranges.lm, "day", at = list(price1 = 0))

# A more sensible model to consider, IMHO (see vignette("interactions"))
org.mlm <- lm(cbind(sales1, sales2) ~ price1 * price2 + day + store,
             data = oranges)
```

pigs

Effects of dietary protein on free plasma leucine concentration in pigs

Description

A two-factor experiment with some observations lost

Usage

pigs

Format

A data frame with 29 observations and 3 variables:

source Source of protein in the diet (factor with 3 levels: fish meal, soybean meal, dried skim milk)

percent Protein percentage in the diet (numeric with 4 values: 9, 12, 15, and 18)

conc Concentration of free plasma leucine, in mcg/ml

Source

Windels HF (1964) PhD thesis, Univ. of Minnesota. (Reported as Problem 10.8 in Oehlert G (2000) *A First Course in Design and Analysis of Experiments*, licensed under Creative Commons, <http://users.stat.umn.edu/~gary/Book.html>.) Observations 7, 22, 23, 31, 33, and 35 have been omitted, creating a more notable imbalance.

Examples

```
pigs.lm <- lm(inverse(conc) ~ source + factor(percent), data = pigs)
emmeans(pigs.lm, "source")
```

plot.emmGrid *Plot an emmGrid or summary_emm object*

Description

Methods are provided to plot EMMs as side-by-side CIs, and optionally to display “comparison arrows” for displaying pairwise comparisons.

Usage

```
## S3 method for class 'emmGrid'
plot(x, y, type, CIs = TRUE, PIs = FALSE,
     comparisons = FALSE, colors, alpha = 0.05, adjust = "tukey",
     int.adjust = "none", intervals, ...)

## S3 method for class 'summary_emm'
plot(x, y, horizontal = TRUE, CIs = TRUE, xlab, ylab,
     facetlab = "label_both", layout, scale = NULL, colors, intervals,
     plotit = TRUE, ...)
```

Arguments

x	Object of class emmGrid or summary_emm
y	(Required but ignored)
type	Character value specifying the type of prediction desired (matching "linear.predictor", "link", or "response"). See details under summary.emmGrid . In addition, the user may specify type = "scale", in which case a transformed scale (e.g., a log scale) is displayed based on the transformation or link function used. Additional customization of this scale is available through including arguments to <code>ggplot2::scale_x_continuous</code> in ...
CIs	Logical value. If TRUE, confidence intervals are plotted for each estimate.
PIs	Logical value. If TRUE, prediction intervals are plotted for each estimate. If object is a Bayesian model, this requires the ... arguments to include <code>frequentist = TRUE</code> and <code>sigma = (some value)</code> . Note that the PIs option is <i>not</i> available with <code>summary_emm</code> objects – only for <code>emmGrid</code> objects. Also, prediction intervals are not available with <code>engine = "lattice"</code> .
comparisons	Logical value. If TRUE, “comparison arrows” are added to the plot, in such a way that the degree to which arrows overlap reflects as much as possible the significance of the comparison of the two estimates. (A warning is issued if this can’t be done.) Note that comparison arrows are not available with ‘summary_emm’ objects.

colors	Optional character vector of colors to use for estimates, CIs, PIs, and comparison arrows, respectively. If missing, these are derived from ink, paper, and accent in the theme's geom element. ink is used for the estimates, accent is used for comparison arrows, and a contrasting color to accent is blended with paper for the intervals. If just one color is given, estimates and intervals are made from various blends of that color and paper, and accent color is used for comparison arrows.
alpha	The significance level to use in constructing comparison arrows
adjust	Character value: Multiplicity adjustment method for comparison arrows <i>only</i> .
int.adjust	Character value: Multiplicity adjustment method for the plotted confidence intervals <i>only</i> .
intervals	If specified, it is used to set CIs. This is the previous argument name for CIs and is provided for backward compatibility.
...	Additional arguments passed to <code>update.emmGrid</code> , <code>summary.emmGrid</code> , <code>predict.emmGrid</code> , or <code>dotplot</code>
horizontal	Logical value specifying whether the intervals should be plotted horizontally or vertically
xlab	Character label for horizontal axis
ylab	Character label for vertical axis
facetlab	Character or function method used to label facets in a multi-panel plot (with the ggplot engine). Default is "label_both", meaning that both factor names and levels are shown, You can use "label_value" to save space, or "label_context" to decide automatically (often wrongly). See the help page for <code>ggplot2::labellers</code>
layout	Numeric value passed to <code>dotplot</code> when <code>engine == "lattice"</code> .
scale	Object of class <code>trans</code> (in the scales package) to specify a nonlinear scale. This is used in lieu of <code>type = "scale"</code> when plotting a <code>summary_emm</code> object created with <code>type = "response"</code> . This is ignored with other types of summaries.
plotit	Logical value. If TRUE, a graphical object is returned; if FALSE, a data.frame is returned containing all the values used to construct the plot.

Value

If `plotit = TRUE`, a graphical object is returned.

If `plotit = FALSE`, a `data.frame` with the table of EMMs that would be plotted. In the latter case, the estimate being plotted is named `.emmmean`, and any factors involved have the same names as in the object. Confidence limits are named `lower.CL` and `upper.CL`, prediction limits are named `lpl` and `upl`, and comparison-arrow limits are named `lcmp1` and `ucmp1`. There is also a variable named `pri.fac` which contains the factor combinations that are *not* among the by variables.

Details

If any by variables are in force, the plot is divided into separate panels. For "summary_emm" objects, the ... arguments in `plot` are passed *only* to `dotplot`, whereas for "emmGrid" objects, the object is updated using ... before summarizing and plotting.

In plots with `comparisons = TRUE`, the resulting arrows are only approximate, and in some cases may fail to accurately reflect the pairwise comparisons of the estimates – especially when estimates having large and small standard errors are intermingled in just the wrong way. Note that the maximum and minimum estimates have arrows only in one direction, since there is no need to compare them with anything higher or lower, respectively. See the [vignette\("xplanations", "emmeans"\)](#) for details on how these are derived.

If `adjust` or `int.adjust` are not supplied, they default to the internal `adjust` setting saved in `pairs(x)` and `x` respectively (see [update.emmGrid](#)).

Note

In order to play nice with the plotting functions, any variable names that are not syntactically correct (e.g., contain spaces) are altered using [make.names](#).

Examples

```
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)
plot(warp.emm)

plot(warp.emm, PIs = TRUE, comparisons = TRUE)

with_emm_options(gg.theme = ggplot2::theme_dark(),
  plot(warp.emm, PIs = TRUE, comparisons = TRUE))

plot(warp.emm, by = NULL, comparisons = TRUE, adjust = "none",
  horizontal = FALSE, colors = "blue")

### Using a transformed scale (also demonstrating 'facetlab' argument)
pigs.lm <- lm(log(conc + 2) ~ source * factor(percent), data = pigs)
pigs.emm <- emmeans(pigs.lm, ~ percent | source)
plot(pigs.emm, type = "scale", breaks = seq(20, 100, by = 10),
  facetlab = "label_value")

# Based on a summary.
# To get a transformed axis, must specify 'scale'; but it does not necessarily
# have to be the same as the actual response transformation
pigs.ci <- confint(pigs.emm, type = "response")
plot(pigs.ci, scale = scales::log10_trans(),
  facetlab = \(x) ggplot2::label_both(x, sep = " = "))
```

pwpm

Pairwise P-value matrix (plus other statistics)

Description

This function presents results from `emmeans` and pairwise comparisons thereof in a compact way. It displays a matrix (or matrices) of estimates, pairwise differences, and P values. The user may opt to exclude any of these via arguments `means`, `diffs`, and `pvals`, respectively. To control the direction

of the pairwise differences, use `reverse`; and to control what appears in the upper and lower triangle(s), use `flip`. Optional arguments are passed to `contrast.emmGrid` and/or `summary.emmGrid`, making it possible to control what estimates and tests are displayed.

Usage

```
pwpm(emm, by, reverse = FALSE, pvals = TRUE, means = TRUE,
      diffs = TRUE, flip = FALSE, digits, ...)
```

Arguments

<code>emm</code>	An <code>emmGrid</code> object
<code>by</code>	Character vector of variable(s) in the grid to condition on. These will create different matrices, one for each level or level-combination. If missing, <code>by</code> is set to <code>emm@misc\$by.vars</code> . Grid factors not in <code>by</code> are the <i>primary</i> factors: whose levels or level combinations are compared pairwise.
<code>reverse</code>	Logical value passed to <code>pairs.emmGrid</code> . Thus, <code>FALSE</code> specifies "pairwise" comparisons (earlier vs. later), and <code>TRUE</code> specifies "revpairwise" comparisons (later vs. earlier).
<code>pvals</code>	Logical value. If <code>TRUE</code> , the pairwise differences of the EMMs are included in each matrix according to <code>flip</code> .
<code>means</code>	Logical value. If <code>TRUE</code> , the estimated marginal means (EMMs) from <code>emm</code> are included in the matrix diagonal(s).
<code>diffs</code>	Logical value. If <code>TRUE</code> , the pairwise differences of the EMMs are included in each matrix according to <code>flip</code> .
<code>flip</code>	Logical value that determines where P values and differences are placed. <code>FALSE</code> places the P values in the upper triangle and differences in the lower, and <code>TRUE</code> does just the opposite.
<code>digits</code>	Integer. Number of digits to display. If missing, an optimal number of digits is determined.
<code>...</code>	Additional arguments passed to <code>contrast.emmGrid</code> and <code>summary.emmGrid</code> . You should <i>not</i> include <code>method</code> here, because pairwise comparisons are always used.

Value

A matrix or 'list' of matrices, one for each 'by' level.

Note

If `emm` is the result of a Bayesian analysis, `pwpm` is based on a frequentist analysis

See Also

A graphical display of essentially the same results is available from [pwpp](#)

Examples

```
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)

pwpm(warp.emm)

# use dot options to specify noninferiority tests
pwpm(warp.emm, by = NULL, side = ">", delta = 5, adjust = "none")
```

pwpp

*Pairwise P-value plot***Description**

Constructs a plot of P values associated with pairwise comparisons of estimated marginal means.

Usage

```
pwpp(emm, method = "pairwise", by, sort = TRUE, values = TRUE,
      rows = ".", xlab, ylab, xsub = "", plim = numeric(0), add.space = 0,
      aes, ...)
```

Arguments

emm	An emmGrid object
method	Character or list. Passed to <code>contrast</code> , and defines the contrasts to be displayed. Any contrast method may be used, provided that each contrast includes one coefficient of 1, one coefficient of -1, and the rest 0. That is, calling <code>contrast(object, method)</code> produces a set of comparisons, each with one estimate minus another estimate.
by	Character vector of variable(s) in the grid to condition on. These will create different panels, one for each level or level-combination. Grid factors not in <code>by</code> are the <i>primary</i> factors: whose levels or level combinations are compared pairwise.
sort	Logical value. If TRUE, levels of the factor combinations are ordered by their marginal means. If FALSE, they appear in order based on the existing ordering of the factor levels involved. Note that the levels are ordered the same way in all panels, and in many cases this implies that the means in any particular panel will <i>not</i> be ordered even when <code>sort = TRUE</code> .
values	Logical value. If TRUE, the values of the EMMs are included in the plot. When there are several side-by-side panels due to <code>by</code> variable(s), the labels showing values start stealing a lot of space from the plotting area; in those cases, it may be desirable to specify FALSE or use <code>rows</code> so that some panels are vertically stacked.

<code>rows</code>	Character vector of which by variable(s) are used to define rows of the panel layout. Those variables in by not included in <code>rows</code> define columns in the array of panels. A "." indicates that only one row is used, so all panels are stacked side-by-side.
<code>xlab</code>	Character label to use in place of the default for the P-value axis.
<code>ylab</code>	Character label to use in place of the default for the primary-factor axis.
<code>xsub</code>	Character label used as caption at the lower right of the plot.
<code>plim</code>	numeric vector of value(s) between 0 and 1. These are included among the observed p values so that the range of tick marks includes at least the range of <code>plim</code> . Choosing <code>plim = c(0, 1)</code> will ensure the widest possible range.
<code>add.space</code>	Numeric value to adjust amount of space used for value labels. Positioning of value labels is tricky, and depends on how many panels and the physical size of the plotting region. This parameter allows the user to adjust the position. Changing it by one unit should shift the position by about one character width (right if positive, left if negative). Note that this interacts with <code>aes\$label</code> below.
<code>aes</code>	optional named list of lists. Entries considered are <code>point</code> , <code>segment</code> , and <code>label</code> , and contents are passed to the respective <code>ggplot2::geom_xxx()</code> functions. These affect rendering of points, line segments joining them, and value labels. Defaults are <code>point = list(size = 2)</code> , <code>segment = list()</code> , and <code>label = list(size = 2.5)</code> .
<code>...</code>	Additional arguments passed to <code>contrast</code> and <code>summary.emmGrid</code> , as well as to <code>geom_segment</code> and <code>geom_label</code>

Details

Factor levels (or combinations thereof) are plotted on the vertical scale, and P values are plotted on the horizontal scale. Each P value is plotted twice – at vertical positions corresponding to the levels being compared – and connected by a line segment. Thus, it is easy to visualize which P values are small and large, and which levels are compared. In addition, factor levels are color-coded, and the points and half-line segments appear in the color of the other level. The P-value scale is nonlinear, so as to stretch-out smaller P values and compress larger ones. P values smaller than 0.0004 are altered and plotted in a way that makes them more distinguishable from one another.

If `xlab`, `ylab`, and `xsub` are not provided, reasonable labels are created. `xsub` is used to note special features; e.g., equivalence thresholds or one-sided tests.

Note

If `emm` is the result of a Bayesian analysis, the plot is based on summaries with `frequentist = TRUE`.

The **ggplot2** and **scales** packages must be installed in order for `pwpp` to work.

Additional plot aesthetics are available by adding them to the returned object; see the examples

See Also

A numerical display of essentially the same results is available from [pwpm](#)

Examples

```
pigs.lm <- lm(log(conc) ~ source * factor(percent), data = pigs)
emm = emmeans(pigs.lm, ~ percent | source)
pwpp(emm)
pwpp(emm, method = "trt.vs.ctrl1", type = "response", side = ">")

# custom aesthetics:
my.aes <- list(point = list(shape = "square"),
               segment = list(linetype = "dashed", color = "red"),
               label = list(family = "serif", fontface = "italic"))
my.pal <- c("darkgreen", "blue", "magenta", "orange")
pwpp(emm, aes = my.aes) + ggplot2::scale_color_manual(values = my.pal)
```

qdrg

*Quick and dirty reference grid***Description**

This function may make it possible to compute a reference grid for a model object that is otherwise not supported.

Usage

```
qdrg(formula, data, coef, vcov, df, mcmc, object, subset, weights, contrasts,
      link, qr, ordinal, ...)
```

```
## Default S3 method:
```

```
qdrg(formula = stats::formula(object),
      data = try(recover_data.lm(object), silent = TRUE),
      coef = stats::coef(object), vcov = stats::vcov(object),
      df = stats::df.residual(object), mcmc, object, subset,
      weights = stats::weights(object), contrasts = object$contrasts,
      link = ifelse(!is.null(lnk <- object$family$link), lnk, object$link),
      qr = object$qr, ordinal, ...)
```

Arguments

formula	Formula for the fixed effects
data	Dataset containing the variables in the model
coef	Fixed-effect regression coefficients (must conform to formula)
vcov	Variance-covariance matrix of the fixed effects
df	Error degrees of freedom
mcmc	Posterior sample of fixed-effect coefficients

object	Optional model object. <i>This rarely works!</i> ; but if provided, we try to set other arguments based on an expectation that ‘object’ has a similar structure to ‘lm’ objects. See Details.
subset	Subset of data used in fitting the model
weights	Weights used in fitting the model
contrasts	List of contrasts specified in fitting the model
link	Link function (character or list) used, if a generalized linear model. (Note: response transformations are auto-detected from formula)
qr	QR decomposition of the model matrix; used only if there are NAs in coef.
ordinal	list with elements dim and mode. ordinal\$dim (integer) is the number of levels in an ordinal response. If ordinal is provided, the intercept terms are modified appropriate to predicting an ordinal response, as described in vignette("models"), Section O, using ordinal\$mode as the mode argument (if not provided, "latent" is assumed). (All modes are supported except ‘scale’) For this to work, we expect the first ordinal\$dim - 1 elements of coef to be the estimated threshold parameters, followed by the coefficients for the linear predictor. Also, if mode requires back-transforming (e.g., "prob" or "mean.class"), the user may need to supply the link for it to work correctly.
...	Optional arguments passed to ref_grid

Details

Usually, you need to provide either `object`; or `formula`, `coef`, `vcov`, `data`, and perhaps other parameters. It is often fairly straightforward to figure out how to get these from the model object; see the documentation for the model class that was fitted. Sometimes one or more of these quantities contains extra parameters, and if so, you may need to subset them to make everything conformable. For a given `formula` and `data`, you can find out what is needed via `colnames(model.matrix(formula, data))`. (However, for an ordinal model, we expect the first `ordinal.dim - 1` coefficients to replace (Intercept). And for a multivariate model, we expect `coef` to be a matrix with these row names, and `vcov` to have as many rows and columns as the total number of elements of `coef`.)

If `object` is specified, this function serves as a generic for dispatching a method for `object`’s class. See the arguments for `qdrG.default` to see how the arguments are determined by default. For many `lm`- or `glm`-like models, it may suffice override just one or two of these defaults. The possibility of a custom `qdrG` method also provides a minimal way for package developers to provide **emmeans** support: it doesn’t allow directly applying `emmeans()` on the model, but at least the user can obtain a reference grid, and then go from there. Note that when using a ‘`qdrG`’ method, it is best for the user to specify ‘`object =`’ explicitly in the call, since ‘`object`’ is not the first argument of ‘`qdrG()`’. However, if the first argument is not a formula, the function is retried with it as `object`.

The functions `qdrG` and `emmobj` are close cousins, in that they both produce `emmGrid` objects. When starting with summary statistics for an existing grid, `emmobj` is more useful, while `qdrG` is more useful when starting from a fitted model.

Value

An `emmGrid` object constructed from the arguments

Rank deficiencies

Different model-fitting packages take different approaches when the model matrix is singular, but `qdrG` tries to reconcile them by comparing the linear functions created by `formula` to `coefs` and `vcov`. We may then use the **estimability** package to determine what quantities are estimable. For reconciling to work properly, `coef` should be named and `vcov` should have `dimnames`. To disable this name-matching action, remove the names from `coef`, e.g., by calling `unname()`. No reconciliation is attempted in multivariate-response cases. For more details on estimability, see the documentation in the **estimability** package.

Note

For backwards compatibility, an argument `ordinal.dim` is invisibly supported as part of `...`, and if present, sets `ordinal = list(dim = ordinal.dim, mode = "latent")`

See Also

[emmobj](#) for an alternative way to construct an `emmGrid`.

Examples

```
# In these examples, use emm_example(..., list = TRUE) # to see just the code

if (require(biglm, quietly = TRUE))
  emm_example("qdrG-biglm")

if(require(coda, quietly = TRUE) && require(lme4, quietly = TRUE))
  emm_example("qdrG-coda")

if(require(ordinal, quietly = TRUE))
  emm_example("qdrG-ordinal")
```

rbind.emmGrid

Combine or subset emmGrid objects

Description

These functions provide methods for `rbind` and `[` that may be used to combine `emmGrid` objects together, or to extract a subset of cases. The primary reason for doing this would be to obtain multiplicity-adjusted results for smaller or larger families of tests or confidence intervals.

Usage

```
## S3 method for class 'emmGrid'
rbind(..., deparse.level = 1, adjust = "bonferroni")

## S3 method for class 'emmGrid'
e1 + e2
```

```

## S3 method for class 'emmGrid'
x[i, adjust, drop.levels = TRUE, ...]

## S3 method for class 'emmGrid'
head(x, n = 6, ...)

## S3 method for class 'emmGrid'
tail(x, n = 6, ...)

## S3 method for class 'emmGrid'
subset(x, subset, ...)

## S3 method for class 'emm_list'
rbind(..., which, adjust = "bonferroni")

## S3 method for class 'summary_emm'
rbind(..., which)

force_regular(object)

```

Arguments

...	In rbind, object(s) of class emmGrid or summary_emm. In others, additional arguments passed to other methods
deparse.level	(required but not used)
adjust	Character value passed to update.emmGrid
e1, e2, x, object	Objects of class emmGrid
i	Integer vector of indexes
drop.levels	Logical value. If TRUE, the "levels" slot in the returned object is updated to hold only the predictor levels that actually occur
n	integer number of entries to include (or exclude if negative)
subset	logical expression indicating which rows of the grid to keep
which	Integer vector of subset of elements to use; if missing, we use all elements.

Value

A revised object of class emmGrid

The result of $e1 + e2$ is the same as `rbind(e1, e2)`

The rbind method for emm_list objects simply combines the emmGrid objects comprising the first element of Note that the returned object is not yet summarized, so any adjust parameters apply to the combined emmGrid.

The rbind method for summary_emm objects (or a list thereof) returns a single summary_emm object. This combined object *preserves* any adjusted P values or confidence limits in the original summaries, since those quantities have already been computed.

force_regular adds extra (invisible) rows to an emmGrid object to make it a regular grid (all combinations of factors). This regular structure is needed by emmeans. An object can become irregular by, for example, subsetting rows, or by obtaining contrasts of a nested structure.

Note

rbind throws an error if there are incompatibilities in the objects' coefficients, covariance structures, etc. But they are allowed to have different factors; a missing level '.' is added to factors as needed.

These functions generally reset by.vars to NULL; so if you want to keep any "by" variables, you should follow-up with `update.emmGrid`.

Examples

```
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
warp.rg <- ref_grid(warp.lm)

# Do all pairwise comparisons within rows or within columns,
# all considered as one family of tests:
w.t <- pairs(emmeans(warp.rg, ~ wool | tension))
t.w <- pairs(emmeans(warp.rg, ~ tension | wool))
rbind(w.t, t.w, adjust = "mvt")
update(w.t + t.w, adjust = "fdr") ## same as above except for adjustment

# Show only 3 of the 6 cases
summary(warp.rg[c(2, 4, 5)])

# After-the-fact 'at' specification
subset(warp.rg, wool == "A") ## or warp.rg |> subset(wool == "A")

### Working with 'emm_list' objects
mod <- lm(conc ~ source + factor(percent), data = pigs)
all <- emmeans(mod, list(src = pairwise ~ source, pct = consec ~ percent))
rbind(all, which = c(2, 4), adjust = "mvt")

### Irregular object
tmp <- warp.rg[-1]
## emmeans(tmp, "tension") # will fail because tmp is irregular
emmeans(force_regular(tmp), "tension") # will show some results
```

ref_grid

Create a reference grid from a fitted model

Description

Using a fitted model object, determine a reference grid for which estimated marginal means are defined. The resulting ref_grid object encapsulates all the information needed to calculate EMMs and make inferences on them.

Usage

```
ref_grid(object, at, cov.reduce = mean,
  cov.keep = get_emm_option("cov.keep"), mult.names, mult.levs,
  options = get_emm_option("ref_grid"), data, df, type, regrid, nesting,
  offset, sigma, counterfactuals, nuisance = character(0), non.nuisance,
  wt.nuis = "equal", rg.limit = get_emm_option("rg.limit"), ...)
```

Arguments

object	An object produced by a supported model-fitting function, such as <code>lm</code> . Many models are supported. See <code>vignette("models", "emmeans")</code> .
at	Optional named list of levels for the corresponding variables
cov.reduce	A function, logical value, or formula; or a named list of these. Each covariate <i>not</i> specified in <code>cov.keep</code> or <code>at</code> is reduced according to these specifications. See the section below on “Using <code>cov.reduce</code> and <code>cov.keep</code> ”.
cov.keep	Character vector: names of covariates that are <i>not</i> to be reduced; these are treated as factors and used in weighting calculations. <code>cov.keep</code> may also include integer value(s), and if so, the maximum of these is used to set a threshold such that any covariate having no more than that many unique values is automatically included in <code>cov.keep</code> .
mult.names	Character value: the name(s) to give to the pseudo-factor(s) whose levels delineate the elements of a multivariate response. If this is provided, it overrides the default name(s) used for <code>class(object)</code> when it has a multivariate response (e.g., the default is “ <code>rep.meas</code> ” for “ <code>mlm</code> ” objects).
mult.levs	A named list of levels for the dimensions of a multivariate response. If there is more than one element, the combinations of levels are used, in <code>expand.grid</code> order. The (total) number of levels must match the number of dimensions. If <code>mult.name</code> is specified, this argument is ignored.
options	If non-NULL, a named list of arguments to pass to <code>update.emmGrid</code> , just after the object is constructed.
data	A data.frame to use to obtain information about the predictors (e.g. factor levels). If missing, then <code>recover_data</code> is used to attempt to reconstruct the data. See the note with <code>recover_data</code> for an important precaution.
df	Numeric value. This is equivalent to specifying <code>options(df = df)</code> . See <code>update.emmGrid</code> .
type	Character value. If provided, this is saved as the “ <code>predict.type</code> ” setting. See <code>update.emmGrid</code> and the section below on prediction types and transformations.
regrid	Character, logical, or list. If non-missing, the reference grid is reconstructed via <code>regrid</code> with the argument <code>transform = regrid</code> . See the section below on prediction types and transformations. <i>Note:</i> This argument was named <code>transform</code> in version 1.7.2 and earlier. For compatibility with old code, <code>transform</code> is still accepted if found among <code>...</code> , as long as it doesn’t match <code>tran</code> .
nesting	If the model has nested fixed effects, this may be specified here via a character vector or named list specifying the nesting structure. Specifying <code>nesting</code> overrides any nesting structure that is automatically detected. See the section below on Recovering or Overriding Model Information.

offset	Numeric scalar value (if a vector, only the first element is used). This may be used to add an offset, or override offsets based on the model. A common usage would be to specify <code>offset = 0</code> for a Poisson regression model, so that predictions from the reference grid become rates relative to the offset that had been specified in the model.
sigma	Numeric value to use for subsequent predictions or back-transformation bias adjustments. If not specified, we use <code>sigma(object)</code> , if available, and <code>NULL</code> otherwise. Note: This applies only when the family is "gaussian"; for other families, <code>sigma</code> is set to <code>NA</code> and cannot be overridden.
counterfactuals	<code>counterfactuals</code> specifies character names of counterfactual factors. If this is non-missing, a reference grid is created consisting of combinations of counterfactual levels and the actual levels of those same factors. This grid is always converted to the response transformation scale and averaged over the actual factor levels. See the section below on counterfactuals.
nuisance, non.nuisance, wt.nuis	If <code>nuisance</code> is a vector of predictor names, those predictors are omitted from the reference grid. Instead, the result will be as if we had averaged over the levels of those factors, with either equal or proportional weights as specified in <code>wt.nuis</code> (see the <code>weights</code> argument in <code>emmeans</code>). The factors in <code>nuisance</code> must not interact with other factors, not even other nuisance factors. Specifying nuisance factors can save considerable storage and computation time, and help avoid exceeding the maximum reference-grid size (<code>get_emm_option("rg.limit")</code>). (Note: For certain models where the <code>emm_basis</code> method returns a re-gridded parameterization, nuisance factors cannot be used, and an error is thrown.)
rg.limit	Integer limit on the number of reference-grid rows to allow (checked before any multivariate responses are included).
...	Optional arguments passed to <code>summary.emmGrid</code> , <code>emm_basis</code> , and <code>recover_data</code> , such as <code>params</code> , <code>vcov</code> . (see Covariance matrix below), or options such as <code>mode</code> for specific model types (see <code>vignette("models", "emmeans")</code>).

Details

To users, the `ref_grid` function itself is important because most of its arguments are in effect arguments of `emmeans` and related functions, in that those functions pass their `...` arguments to `ref_grid`.

The reference grid consists of combinations of independent variables over which predictions are made. Estimated marginal means are defined as these predictions, or marginal averages thereof. The grid is determined by first reconstructing the data used in fitting the model (see `recover_data`), or by using the `data.frame` provided in `data`.

By “independent variables,” we mean (in most cases) the results of `all.vars()` applied to the fixed-effects part of the right-hand side of the model formula. Any random effects are excluded. Thus, if the model formula in an `lme4::lmer` call is `yield ~ fert + seed*density + log(rain) + (1|block/plot)`, the independent variables are `fert`, `seed`, `density`, and `rain` (not `log(rain)`). In multivariate models, the dimension of the multivariate response is also considered an independent variable.

The default reference grid is determined by the observed levels of any factors, the ordered unique values of character-valued predictors, and the results of `cov.reduce` for numeric predictors. These may be overridden using `at`. See also the section below on recovering/overriding model information.

Value

An object of the S4 class "emmGrid" (see [emmGrid-class](#)). These objects encapsulate everything needed to do calculations and inferences for estimated marginal means, and contain nothing that depends on the model-fitting procedure.

Using `cov.reduce` and `cov.keep`

The `cov.keep` argument was not available in **emmeans** versions 1.4.1 and earlier. Any covariates named in this list are treated as if they are factors: all the unique levels are kept in the reference grid. The user may also specify an integer value, in which case any covariate having no more than that number of unique values is implicitly included in `cov.keep`. The default for `cov.keep` is set and retrieved via the [emm_options](#) framework, and the system default is "2", meaning that covariates having only two unique values are automatically treated as two-level factors. See also the Note below on backward compatibility.

There is a subtle distinction between including a covariate in `cov.keep` and specifying its values manually in `at`: Covariates included in `cov.keep` are treated as factors for purposes of weighting, while specifying levels in `at` will not include the covariate in weighting. See the `mtcars.lm` example below for an illustration.

`cov.reduce` may be a function, logical value, formula, or a named list of these. If a single function, it is applied to each covariate. If logical and TRUE, `mean` is used. If logical and FALSE, it is equivalent to including all covariates in `cov.keep`. Use of '`cov.reduce = FALSE`' is inadvisable because it can result in a huge reference grid; it is far better to use `cov.keep`.

If a formula (which must be two-sided), then a model is fitted to that formula using `lm`; then in the reference grid, its response variable is set to the results of `predict` for that model, with the reference grid as `newdata`. (This is done *after* the reference grid is determined.) A formula is appropriate here when you think experimental conditions affect the covariate as well as the response.

To allow for situations where a simple `lm()` call as described above won't be adequate, a formula of the form `ext ~ fcname` is also supported, where the left-hand side may be `ext`, `extern`, or `external` (and must *not* be a predictor name) and the right-hand side is the name of an existing function. The function is called with one argument, a data frame with columns for each variable in the reference grid. The function is expected to use that frame as new data to be used to obtain predictions for one or more models; and it should return a named list or data frame with replacement values for one or more of the covariates.

If `cov.reduce` is a named list, then the above criteria are used to determine what to do with covariates named in the list. (However, formula elements do not need to be named, as those names are determined from the formulas' left-hand sides.) Any unresolved covariates are reduced using "mean".

Any `cov.reduce` or `cov.keep` specification for a covariate also named in `at` is ignored.

Interdependent covariates

Care must be taken when covariate values depend on one another. For example, when a polynomial model was fitted using predictors x , x^2 (equal to x^2), and x^3 (equal to x^3), the reference grid will by default set x^2 and x^3 to their means, which is inconsistent. The user should instead use the `at` argument to set these to the square and cube of $\text{mean}(x)$. Better yet, fit the model using a formula involving `poly(x, 3)` or `I(x^2)` and `I(x^3)`; then there is only x appearing as a covariate; it will be set to its mean, and the model matrix will have the correct corresponding quadratic and cubic terms.

Matrix covariates

Support for covariates that appear in the dataset as matrices is very limited. If the matrix has but one column, it is treated like an ordinary covariate. Otherwise, with more than one column, each column is reduced to a single reference value – the result of applying `cov.reduce` to each column (averaged together if that produces more than one value); you may not specify values in `at`; and they are not treated as variables in the reference grid, except for purposes of obtaining predictions.

Recovering or overriding model information

Ability to support a particular class of object depends on the existence of `recover_data` and `emm_basis` methods – see [extending-emmeans](#) for details. The call methods(`"recover_data"`) will help identify these.

Data. In certain models, (e.g., results of `glmer.nb`), it is not possible to identify the original dataset. In such cases, we can work around this by setting `data` equal to the dataset used in fitting the model, or a suitable subset. Only the complete cases in `data` are used, so it may be necessary to exclude some unused variables. Using `data` can also help save computing, especially when the dataset is large. In any case, `data` must represent all factor levels used in fitting the model. It *cannot* be used as an alternative to `at`. (Note: If there is a pattern of NAs that caused one or more factor levels to be excluded when fitting the model, then `data` should also exclude those levels.)

Covariance matrix. By default, the variance-covariance matrix for the fixed effects is obtained from object, usually via its `vcov` method. However, the user may override this via a `vcov` argument, specifying a matrix or a function. If a matrix, it must be square and of the same dimension and parameter order of the fixed effects. If a function, must return a suitable matrix when it is called with arguments (`object, ...`). Be careful with possible unintended conflicts with arguments in `...`; for example, `sandwich::vcovHAC()` has optional arguments `adjust` and `weights` that may be intended for `emmmeans()` but will also be passed to `vcov()`.

Nested factors. Having a nesting structure affects marginal averaging in `emmmeans` in that it is done separately for each level (or combination thereof) of the grouping factors. `ref_grid` tries to discern which factors are nested in other factors, but it is not always obvious, and if it misses some, the user must specify this structure via `nesting`; or later using `update.emmGrid`. The `nesting` argument may be a character vector, a named list, or NULL. If a list, each name should be the name of a single factor in the grid, and its entry a character vector of the name(s) of its grouping factor(s). `nesting` may also be a character value of the form `"factor1 %in% (factor2*factor3)"` (the parentheses are optional). If there is more than one such specification, they may be appended separated by commas, or as separate elements of a character vector. For example, these specifications are equivalent: `nesting = list(state = "country", city = c("state", "country"))`, `nesting = "state %in% country, city %in% (state*country)"`, and `nesting = c("state %in% country", "city %in% state*country")`.

Predictors with subscripts and data-set references

When the fitted model contains subscripts or explicit references to data sets, the reference grid may optionally be post-processed to simplify the variable names, depending on the `simplify.names` option (see `emm_options`), which by default is `TRUE`. For example, if the model formula is `data1$resp ~ data1$trt + data2[[3]] + data2[["cov"]]`, the simplified predictor names (for use, e.g., in the specs for `emmeans`) will be `trt`, `data2[[3]]`, and `cov`. Numerical subscripts are not simplified; nor are variables having simplified names that coincide, such as if `data2$trt` were also in the model.

Please note that this simplification is performed *after* the reference grid is constructed. Thus, non-simplified names must be used in the `at` argument (e.g., `at = list(`data2["cov"]` = 2:4)`).

If you don't want names simplified, use `emm_options(simplify.names = FALSE)`.

Prediction types and transformations

Transformations can exist because of a link function in a generalized linear model, or as a response transformation, or even both. In many cases, they are auto-detected, for example a model formula of the form `sqrt(y) ~ ...`. Even transformations containing multiplicative or additive constants, such as `2*sqrt(y + pi) ~ ...`, are auto-detected. A response transformation of `y + 1 ~ ...` is *not* auto-detected, but `I(y + 1) ~ ...` is interpreted as `identity(y + 1) ~ ...`. A warning is issued if it gets too complicated. Complex transformations like the Box-Cox transformation are not auto-detected; but see the help page for `make_tran` for information on some advanced methods.

There is a subtle difference between specifying `'type = "response"'` and `'regrid = "response"'`. While the summary statistics for the grid itself are the same, subsequent use in `emmeans` will yield different results if there is a response transformation or link function. With `'type = "response"'`, EMMs are computed by averaging together predictions on the *linear-predictor* scale and then back-transforming to the response scale; while with `'regrid = "response"'`, the predictions are already on the response scale so that the EMMs will be the arithmetic means of those response-scale predictions. To add further to the possibilities, *geometric* means of the response-scale predictions are obtainable via `'regrid = "log", type = "response"'`. See also the help page for `regrid`.

Order-of-processing issues: The `regrid` argument, if present, is acted on immediately after the reference grid is constructed, while some of the `...` arguments may be used to update the object at the very end. Thus, code like `ref_grid(mod, tran = "sqrt", regrid = "response")` will not work correctly if the intention was to specify the response transformation, because the re-grid is done *before* it processes `tran = "sqrt"`. To get the intended result, do `regrid(ref_grid(mod, tran = "sqrt"), transform = "response")`.

Counterfactuals

If `counterfactuals` is specified, the rows of the entire dataset become part of the reference grid, and the other reference levels are confined to those named in `counterfactuals`. In this type of analysis (called G-computation), we substitute (or impute) each combination of counterfactual levels into the entire dataset. Thus, predictions from this grid are those of each observation under each of the counterfactual levels. For this to make sense, we require an assumption of exchangeability of these levels.

This grid is always converted to the response scale, as G-computation on the linear-predictor scale produces the same results as ordinary weighted EMMs. If we have counterfactual factors `A`, `B`, the reference grid also includes factors `actual_A`, `actual_B` which are used to track which observations originally had the `A`, `B` levels before they were changed by the counterfactuals code. We

average the response-scale predictions for each combination of actual levels and imputed levels (and multivariate levels, if any). See additional discussion of how `emmeans` handles counterfactuals under that documentation.

Currently, counterfactuals are not supported when the reference grid requires post-processing (e.g., ordinal models with `mode = "prob"`). Cases where we have nested factor levels can be complicated if mixed-in with counterfactuals, and we make no guarantees. Note that past implementations included arguments `wt.counter` and `avg.counter`, which are now deprecated and are just ignored if specified.

Optional side effect

If the `save.ref_grid` option is set to `TRUE` (see `emm_options`), The most recent result of `ref_grid`, whether called directly or indirectly via `emmeans`, `emtrends`, or some other function that calls one of these, is saved in the user's environment as `.Last.ref_grid`. This facilitates checking what reference grid was used, or reusing the same reference grid for further calculations. This automatic saving is disabled by default, but may be enabled via `'emm_options(save.ref_grid = TRUE)'`.

Note

The system default for `cov.keep` causes models containing indicator variables to be handled differently than in `emmeans` version 1.4.1 or earlier. To replicate older analyses, change the default via `'emm_options(cov.keep = character(0))'`.

Some earlier versions of `emmeans` offer a `covnest` argument. This is now obsolete; if `covnest` is specified, it is harmlessly ignored. Cases where it was needed are now handled appropriately via the code associated with `cov.keep`.

See Also

Reference grids are of class `emmGrid`, and several methods exist for them – for example `summary.emmGrid`. Reference grids are fundamental to `emmeans`. Supported models are detailed in `vignette("models", "emmeans")`. See `update.emmGrid` for details of arguments that can be in options (or in ...).

Examples

```
fiber.lm <- lm(strength ~ machine*diameter, data = fiber)
ref_grid(fiber.lm)

ref_grid(fiber.lm, at = list(diameter = c(15, 25)))

## Not run:
# We could substitute the sandwich estimator vcovHAC(fiber.lm)
# as follows:
summary(ref_grid(fiber.lm, vcov. = sandwich::vcovHAC))

## End(Not run)

# If we thought that the machines affect the diameters
# (admittedly not plausible in this example), then we should use:
ref_grid(fiber.lm, cov.reduce = diameter ~ machine)
```

```

### Model with indicator variables as predictors:
mtcars.lm <- lm(mpg ~ disp + wt + vs * am, data = mtcars)
(rg.default <- ref_grid(mtcars.lm))
(rg.nokeep <- ref_grid(mtcars.lm, cov.keep = character(0)))
(rg.at <- ref_grid(mtcars.lm, at = list(vs = 0:1, am = 0:1)))

# Two of these have the same grid but different weights:
rg.default@grid
rg.at@grid

### Using cov.reduce formulas...
# Above suggests we can vary disp indep. of other factors - unrealistic
rg.alt <- ref_grid(mtcars.lm, at = list(wt = c(2.5, 3, 3.5)),
  cov.reduce = disp ~ vs * wt)
rg.alt@grid

# Alternative to above where we model sqrt(disp)
disp.mod <- lm(sqrt(disp) ~ vs * wt, data = mtcars)
disp.fun <- function(dat)
  list(disp = predict(disp.mod, newdata = dat)^2)
rg.alt2 <- ref_grid(mtcars.lm, at = list(wt = c(2.5, 3, 3.5)),
  cov.reduce = external ~ disp.fun)
rg.alt2@grid

# Multivariate example
MOats.lm = lm(yield ~ Block + Variety, data = MOats)
ref_grid(MOats.lm, mult.names = "nitro")
# Silly illustration of how to use 'mult.levs' to make comb's of two factors
ref_grid(MOats.lm, mult.levs = list(T=LETTERS[1:2], U=letters[1:2]))

# Comparing estimates with and without counterfactuals
neuralgia.glm <- glm(Pain ~ Treatment + Sex + Age + Duration,
  family = binomial(), data = neuralgia)
emmeans(neuralgia.glm, "Treatment", type = "response")

emmeans(neuralgia.glm, "Treatment", counterfactuals = "Treatment")

# Using 'params'
require("splines")
my.knots = c(2.5, 3, 3.5)
mod = lm(Sepal.Length ~ Species * ns(Sepal.Width, knots = my.knots), data = iris)
## my.knots is not a predictor, so need to name it in 'params'
ref_grid(mod, params = "my.knots")

```

Description

The typical use of this function is to cause EMMs to be computed on a different scale, e.g., the back-transformed scale rather than the linear-predictor scale. In other words, if you want back-transformed results, do you want to average and then back-transform, or back-transform and then average?

Usage

```
regrid(object, transform = c("response", "mu", "unlink", "none", "pass",
  links), inv.link.lbl = "response", predict.type,
  bias.adjust = get_emm_option("back.bias.adj"), sigma, N.sim,
  sim = mvtnorm::rmvnorm, ...)
```

Arguments

object	An object of class <code>emmGrid</code>
transform	Character, list, or logical value. If "response", "mu", or TRUE, the inverse transformation is applied to the estimates in the grid (but if there is both a link function and a response transformation, "mu" back-transforms only the link part); if "none" or FALSE, object is re-gridded so that its <code>bhat</code> slot contains <code>predict(object)</code> and its <code>linfct</code> slot is the identity. Any internal transformation information is preserved. If <code>transform = "pass"</code> , the object is not re-gridded in any way (this may be useful in conjunction with <code>N.sim</code>). If <code>transform</code> is a character value in <code>links</code> (which is the set of valid arguments for the <code>make.link</code> function, excepting "identity"), or if <code>transform</code> is a list of the same form as returned by <code>make.links</code> or <code>make.tran</code> , the results are formulated as if the response had been transformed with that link function.
inv.link.lbl	Character value. This applies only when <code>transform</code> is in <code>links</code> , and is used to label the predictions if subsequently summarized with <code>type = "response"</code> .
predict.type	Character value. If provided, the returned object is updated with the given type to use by default by <code>summary.emmGrid</code> (see <code>update.emmGrid</code>). This may be useful if, for example, when one specifies <code>transform = "log"</code> but desires summaries to be produced by default on the response scale.
bias.adjust	Logical value for whether to adjust for bias in back-transforming (<code>transform = "response"</code>). This requires a valid value of <code>sigma</code> to exist in the object or be specified.
sigma	Error SD assumed for bias correction (when <code>transform = "response"</code> and a transformation is in effect). If not specified, <code>object@misc\$sigma</code> is used, and a warning is issued if it is not found.
N.sim	Integer value. If specified and object is based on a frequentist model (i.e., does not have a posterior sample), then a fake posterior sample is generated using the function <code>sim</code> .
sim	A function of three arguments (no names are assumed). If <code>N.sim</code> is supplied with a frequentist model, this function is called with respective arguments <code>N.sim</code> , <code>object@bhat</code> , and <code>object@V</code> . The default is the multivariate normal distribution.
...	Ignored.

Details

The `regrid` function reparameterizes an existing `ref.grid` so that its `linfct` slot is the identity matrix and its `bhat` slot consists of the estimates at the grid points. If `transform` is `TRUE`, the inverse transform is applied to the estimates. Outwardly, when `transform = "response"`, the result of `summary.emmGrid` after applying `regrid` is identical to the summary of the original object using `'type="response"'`. But subsequent EMMs or contrasts will be conducted on the new scale – which is the reason this function exists.

This function may also be used to simulate a sample of regression coefficients for a frequentist model for subsequent use as though it were a Bayesian model. To do so, specify a value for `N.sim` and a sample is simulated using the function `sim`. The grid may be further processed in accordance with the other arguments; or if `transform = "pass"`, it is simply returned with the only change being the addition of the simulated sample.

Value

An `emmGrid` object with the requested changes

Degrees of freedom

In cases where the degrees of freedom depended on the linear function being estimated (e.g., Satterthwaite method), the d.f. from the reference grid are saved, and a kind of “containment” method is substituted in the returned object, whereby the calculated d.f. for a new linear function will be the minimum d.f. among those having nonzero coefficients. This is kind of an *ad hoc* method, and it can over-estimate the degrees of freedom in some cases. An annotation is displayed below any subsequent summary results stating that the degrees-of-freedom method is inherited from the previous method at the time of re-gridding.

Note

Another way to use `regrid` is to supply a `regrid` argument to `ref.grid` (either directly or indirectly via `emmeans`), in which case its value is passed to `regrid` as `transform`. This is often a simpler approach if the reference grid has not already been constructed.

Examples

```
pigs.lm <- lm(log(conc) ~ source + factor(percent), data = pigs)
rg <- ref_grid(pigs.lm)

# This will yield EMMs as GEOMETRIC means of concentrations:
(emm1 <- emmeans(rg, "source", type = "response"))
pairs(emm1) ## We obtain RATIOS

# This will yield EMMs as ARITHMETIC means of concentrations:
(emm2 <- emmeans(regrid(rg, transform = "response"), "source"))
pairs(emm2) ## We obtain DIFFERENCES
# Same result, useful if we hadn't already created 'rg'
# emm2 <- emmeans(pigs.lm, "source", regrid = "response")

# Simulate a sample of regression coefficients
set.seed(2.71828)
```

```
rgb <- regrid(rg, N.sim = 200, transform = "pass")
emmmeans(rgb, "source", type = "response") ## similar to emm1
```

str.emmGrid

Miscellaneous methods for emmGrid objects

Description

Miscellaneous methods for emmGrid objects

Usage

```
## S3 method for class 'emmGrid'
str(object, ...)

## S3 method for class 'emmGrid'
print(x, ..., export = FALSE)

## S3 method for class 'emmGrid'
vcov(object, ..., sep = get_emm_option("sep"))

linfct(object, ...)

## Default S3 method:
linfct(object, ...)
```

Arguments

object	An emmGrid object
...	(required but not used)
x	An emmGrid object
export	Logical value. If FALSE, the object is printed. If TRUE, a list is invisibly returned, which contains character elements named <code>summary</code> and <code>annotations</code> that may be saved or displayed as the user sees fit. <code>summary</code> is a character matrix (or list of such matrices, if a by variable is in effect). <code>annotations</code> is a character vector of the annotations that would have been printed below the summary or summaries.
sep	separator for pasting levels in creating row and column names for <code>vcov()</code> results

Value

The `vcov` method returns a symmetric matrix of variances and covariances for `predict.emmGrid(object, type = "lp")`

The `linfct` function and method returns the `linfct` slot of object.

Examples

```
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)
vcov(warp.emm) |> zapsmall()

vcov(pairs(warp.emm), sep = "|") |> zapsmall()
```

summary.emmGrid

Summaries, predictions, intervals, and tests for emmGrid objects

Description

These are the primary methods for obtaining numerical or tabular results from an `emmGrid` object. `summary.emmGrid` is the general function for summarizing `emmGrid` objects. It also serves as the print method for these objects; so for convenience, `summary()` arguments may be included in calls to functions such as `emmeans` and `contrast` that construct `emmGrid` objects. Note that by default, summaries for Bayesian models are diverted to `hpd.summary`.

Usage

```
## S3 method for class 'emmGrid'
summary(object, infer, level, adjust, by,
  cross.adjust = "none", type, df, calc, null, delta, side, frequentist,
  bias.adjust = get_emm_option("back.bias.adj"), sigma, ...)

## S3 method for class 'emmGrid'
confint(object, parm, level = 0.95, ...)

test(object, null, ...)

## S3 method for class 'emmGrid'
test(object, null = 0, joint = FALSE, verbose = FALSE,
  rows, by, status = FALSE, ...)

## S3 method for class 'emmGrid'
predict(object, type, interval = c("none", "confidence",
  "prediction"), level = 0.95,
  bias.adjust = get_emm_option("back.bias.adj"), sigma, ...)

## S3 method for class 'emmGrid'
as.data.frame(x, row.names = NULL, optional,
  check.names = TRUE, destroy.annotations = FALSE, ...)

## S3 method for class 'summary_emm'
x[... , as.df = FALSE]
```

Arguments

object	An object of class "emmGrid" (see emmGrid-class)
infer	A vector of one or two logical values. The first determines whether confidence intervals are displayed, and the second determines whether <i>t</i> tests and <i>P</i> values are displayed. If only one value is provided, it is used for both.
level	Numerical value between 0 and 1. Confidence level for confidence intervals, if <code>infer[1]</code> is TRUE.
adjust	Character value naming the method used to adjust <i>p</i> values or confidence limits; or to adjust comparison arrows in plot. See the P-value adjustments section below.
by	Character name(s) of variables to use for grouping into separate tables. This affects the family of tests considered in adjusted <i>P</i> values.
cross.adjust	Character: <i>p</i> -value adjustment method to additionally apply <i>across</i> the by groups. See the section on P-value adjustments for details.
type	Character: type of prediction desired. This only has an effect if there is a known transformation or link function. "response" specifies that the inverse transformation be applied. "mu" (or equivalently, "unlink") is usually the same as "response", but in the case where the model has both a link function and a response transformation, only the link part is back-transformed. Other valid values are "link", "lp", and "linear.predictor"; these are equivalent, and request that results be shown for the linear predictor, with no back-transformation. The default is "link", unless the "predict.type" option is in force; see emm_options , and also the section below on transformations and links.
df	Numeric. If non-missing, a constant number of degrees of freedom to use in constructing confidence intervals and <i>P</i> values (NA specifies asymptotic results).
calc	Named list of character value(s) or formula(s). The expressions in char are evaluated and appended to the summary, just after the df column. The expression may include any names up through df in the summary, any additional names in <code>object@grid</code> (such as <code>.wgt.</code> or <code>.offset.</code>), or any earlier elements of calc.
null	Numeric. Null hypothesis value(s), on the linear-predictor scale, against which estimates are tested. May be a single value used for all, or a numeric vector of length equal to the number of tests in each family (i.e., by group in the displayed table).
delta	Numeric value (on the linear-predictor scale). If zero, ordinary tests of significance are performed. If positive, this specifies a threshold for testing equivalence (using the TOST or two-one-sided-test method), non-inferiority, or non-superiority, depending on side. See Details for how the test statistics are defined.
side	Numeric or character value specifying whether the test is left-tailed (-1, "-", "<", "left", or "noninferiority"); right-tailed (1, "+", ">", "right", or "noninferiority"); or two-sided (0, 2, "!=", "two-sided", "both", "equivalence", or "="). See the special section below for more details.

frequentist	Ignored except if a Bayesian model was fitted. If missing or FALSE, the object is passed to hpd.summary . Otherwise, a logical value of TRUE will have it return a frequentist summary.
bias.adjust	Logical value for whether to adjust for bias in back-transforming (type = "response"). This requires a valid value of sigma to exist in the object or be specified.
sigma	Error SD assumed for bias correction (when type = "response" and a transformation is in effect), or for constructing prediction intervals. If not specified, object@misc\$sigma is used, and a warning is issued if it is not found or not valid. <i>Note:</i> sigma may be a vector, but be careful that it correctly corresponds (perhaps after recycling) to the order of the reference grid.
...	Optional arguments such as scheffe.rank (see "P-value adjustments"). In confint.emmGrid, predict.emmGrid, and test.emmGrid, these arguments are passed to summary.emmGrid.
parm	(Required argument for confint methods, but not used)
joint	Logical value. If FALSE, the arguments are passed to summary.emmGrid with infer=c(FALSE, TRUE). If joint = TRUE, a joint test of the hypothesis $L\beta = \text{null}$ is performed, where L is <code>linfct(object)</code> and beta is the vector of fixed effects estimated by <code>object@betahat</code> . This will be either an <i>F</i> test or a chi-square (Wald) test depending on whether degrees of freedom are available. See also joint_tests .
verbose	Logical value. If TRUE and joint = TRUE, a table of the effects being tested is printed.
rows	Integer values. The rows of L to be tested in the joint test. If missing, all rows of L are used. If not missing, by variables are ignored.
status	logical. If TRUE, a note column showing status flags (for rank deficiencies and estimability issues) is displayed even when empty. If FALSE, the column is included only if there are such issues.
interval	Type of interval desired (partial matching is allowed): "none" for no intervals, otherwise confidence or prediction intervals with given arguments, via confint.emmGrid . Note: prediction intervals are not available unless the model family is "gaussian".
x	object of the given class
row.names	passed to as.data.frame
optional	required argument, but ignored in <code>as.data.frame.emmGrid</code>
check.names	passed to data.frame
destroy.annotations	Logical value. If FALSE, an object of class <code>summary_emm</code> is returned (which inherits from <code>data.frame</code>), but if displayed, details like confidence levels, P-value adjustments, transformations, etc. are also shown. But unlike the result of <code>summary</code> , the number of digits displayed is obtained from <code>getOption("digits")</code> rather than using the optimal digits algorithm we usually use. Thus, it is formatted more like a regular data frame, but with any annotations and groupings still intact. If TRUE (not recommended), a "plain vanilla" data frame is returned, based on <code>row.names</code> and <code>check.names</code> .

`as.df` Logical value. With `x[... , as.df = TRUE]`, the result is object is coerced to a `data.frame` before the subscripting is applied. With `as.df = FALSE`, the result is returned as a `summary_emm` object when possible.

Details

`confint.emmGrid` is equivalent to `summary.emmGrid` with `infer = c(TRUE, FALSE)`. The function `test.emmGrid`, when called with `joint = FALSE`, is equivalent to `summary.emmGrid` with `infer = c(FALSE, TRUE)`.

With `joint = TRUE`, `test.emmGrid` calculates the Wald test of the hypothesis `linfct %*% bhat = null`, where `linfct` and `bhat` refer to slots in object (possibly subsetted according to `by` or `rows`). An error is thrown if any row of `linfct` is non-estimable. It is permissible for the rows of `linfct` to be linearly dependent, as long as `null == 0`, in which case a reduced set of contrasts is tested. Linear dependence and nonzero null cause an error. The returned object has an additional `"est.fcns"` attribute, which is a list of the linear functions associated with the joint test.

Value

`summary.emmGrid`, `confint.emmGrid`, and `test.emmGrid` return an object of class `"summary_emm"`, which is an extension of `data.frame` but with a special print method that displays it with custom formatting. For models fitted using MCMC methods, the call is diverted to `hpd.summary` (with `prob` set to `level`, if specified); one may alternatively use general MCMC summarization tools with the results of `as.mcmc`.

`predict` returns a vector of predictions for each row of `object@grid`.

The `as.data.frame` method returns an object that inherits from `"data.frame"`.

Defaults

The `misc` slot in object may contain default values for `by`, `calc`, `infer`, `level`, `adjust`, `type`, `null`, `side`, and `delta`. These defaults vary depending on the code that created the object. The `update` method may be used to change these defaults. In addition, any options set using `'emm_options(summary = ...)'` will trump those stored in the object's `misc` slot.

Transformations and links

With `type = "response"`, the transformation assumed can be found in `'object@misc$tran'`, and its label, for the summary is in `'object@misc$inv.lbl'`. Any t or z tests are still performed on the scale of the linear predictor, not the inverse-transformed one. Similarly, confidence intervals are computed on the linear-predictor scale, then inverse-transformed.

Be aware that only univariate transformations and links are supported in this way. Some multivariate transformations are supported by `mvregrid`.

Bias adjustment when back-transforming

When `bias.adjust` is `TRUE`, then back-transformed estimates are adjusted by adding $0.5h''(u)\sigma^2$, where h is the inverse transformation and u is the linear predictor. This is based on a second-order Taylor expansion. There are better or exact adjustments for certain specific cases, and these may be incorporated in future updates.

Note: In certain models, e.g., those with non-gaussian families, `sigma` is initialized as NA, and so by default, bias adjustment is skipped and a warning is issued. You may override this by specifying a value for `sigma`. However, *with ordinary generalized linear models, bias adjustment is inappropriate* and you should not try to do it. With GEEs and GLMMs, you probably should *not* use `sigma(model)`, and instead you should create an appropriate value using the estimated random effects, e.g., from `VarCorr(model)`. An example is provided in the “transformations” vignette.

A word of caution: This bias-adjustment method is merely a one-term correction, and it multiplies σ^2 . When `sigma` is reasonably small relative to the scale of the response, this is fine; but when `sigma` is large, this bias adjustment can produce bizarre and out-of-range results. Consider for example a logit or probit model where the back-transformed response is constrained to the interval $[0, 1]$; if `sigma` is more than 1, the adjustment can easily pull the estimate outside of these constraints.

P-value adjustments

The `adjust` argument specifies a multiplicity adjustment for tests or confidence intervals. This adjustment always is applied *separately* to each table or sub-table that you see in the printed output (see `rbind.emmGrid` for how to combine tables). If there are non-estimable cases in a by group, those cases are *excluded* before determining the adjustment; that means there could be different adjustments in different groups.

The valid values of `adjust` are as follows:

- "tukey" Uses the Studentized range distribution with the number of means in the family. (Available for two-sided cases only.)
- "scheffe" Computes p values from the F distribution, according to the Scheffe critical value of $\sqrt{rF(\alpha; r, d)}$, where d is the error degrees of freedom and r is the rank of the set of linear functions under consideration. By default, the value of r is computed from `linfct(object)` for each by group; however, if the user specifies an argument matching `scheffe.rank`, its value will be used instead. Ordinarily, if there are k means involved, then $r = k - 1$ for a full set of contrasts involving all k means, and $r = k$ for the means themselves. (The Scheffe adjustment is available for two-sided cases only.)
- "sidak" Makes adjustments as if the estimates were independent (a conservative adjustment in many cases).
- "bonferroni" Multiplies p values, or divides significance levels by the number of estimates. This is a conservative adjustment.
- "dunnetttx" Uses our own *ad hoc* approximation to the Dunnett distribution for a family of estimates having pairwise correlations of 0.5 (as is true when comparing treatments with a control with equal sample sizes). The accuracy of the approximation improves with the number of simultaneous estimates, and is much faster than "mvt". (Available for two-sided cases only.)
- "mvt" Uses the multivariate t distribution to assess the probability or critical value for the maximum of k estimates. This method produces the same p values and intervals as the default `summary` or `confint` methods to the results of `as.glht`. In the context of pairwise comparisons or comparisons with a control, this produces “exact” Tukey or Dunnett adjustments, respectively. However, the algorithm (from the `mvtnorm` package) uses a Monte Carlo method, so results are not exactly repeatable unless the same random-number seed is used (see `set.seed`). As the family size increases, the required computation time will become noticeable or even intolerable, making the "tukey", "dunnetttx", or others more attractive.

"none" Makes no adjustments to the p values.

For tests, not confidence intervals, the Bonferroni-inequality-based adjustment methods in `p.adjust` are also available (currently, these include "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", and "none"). If a `p.adjust.methods` method other than "bonferroni" or "none" is specified for confidence limits, the straight Bonferroni adjustment is used instead. Also, if an adjustment method is not appropriate (e.g., using "tukey" with one-sided tests, or with results that are not pairwise comparisons), a more appropriate method (usually "sidak") is substituted.

In some cases, confidence and p -value adjustments are only approximate – especially when the degrees of freedom or standard errors vary greatly within the family of tests. The "mvt" method is always the correct one-step adjustment, but it can be very slow. One may use `as.glht` with methods in the **multcomp** package to obtain non-conservative multi-step adjustments to tests.

Warning: Non-estimable cases are *included* in the family to which adjustments are applied. You may wish to subset the object using the `[]` operator to work around this problem.

The `cross.adjust` argument is a way of specifying a multiplicity adjustment across the by groups (otherwise by default, each group is treated as a separate family in regards to multiplicity adjustments). It applies only to p values. Valid options are one of the `p.adjust.methods` or "sidak". This argument is ignored unless it is other than "none", there is more than one by group, and they are all the same size. Under those conditions, we first use `adjust` to determine the within-group adjusted p values. Imagine each group's adjusted p values arranged in side-by-side columns, thus forming a matrix with the number of columns equal to the number of by groups. Then we use the `cross.adjust` method to further adjust the adjusted p values in each row of this matrix. Note that an *overall* Bonferroni (or Sidak) adjustment is obtainable by specifying *both* `adjust` and `cross.adjust` as "bonferroni" (or "sidak"). However, less conservative (but yet conservative) overall adjustments are available when it is possible to use an "exact" within-group method (e.g., `adjust = "tukey"` for pairwise comparisons) and `cross.adjust` as a conservative adjustment. [`cross.adjust` methods other than "none", "bonferroni", or "sidak" do not seem advisable, but other `p.adjust` methods are available if you can make sense of them.]

Tests of significance, nonsuperiority, noninferiority, or equivalence

When $\delta = 0$, test statistics are the usual tests of significance. They are of the form '(estimate - null)/SE'. Notationally:

Significance $H_0 : \theta = \theta_0$ versus

$H_1 : \theta < \theta_0$ (left-sided), or

$H_1 : \theta > \theta_0$ (right-sided), or

$H_1 : \theta \neq \theta_0$ (two-sided)

The test statistic is

$$t = (Q - \theta_0) / SE$$

where Q is our estimate of θ ; then left, right, or two-sided p values are produced, depending on side.

When δ is positive, the test statistic depends on side as follows.

Left-sided (nonsuperiority) $H_0 : \theta \geq \theta_0 + \delta$ versus $H_1 : \theta < \theta_0 + \delta$

$$t = (Q - \theta_0 - \delta) / SE$$

The p value is the lower-tail probability.

Right-sided (noninferiority) $H_0 : \theta \leq \theta_0 - \delta$ versus $H_1 : \theta > \theta_0 - \delta$

$$t = (Q - \theta_0 + \delta) / SE$$

The p value is the upper-tail probability.

Two-sided (equivalence) $H_0 : |\theta - \theta_0| \geq \delta$ versus $H_1 : |\theta - \theta_0| < \delta$

$$t = (|Q - \theta_0| - \delta) / SE$$

The p value is the *lower*-tail probability.

Note that t is the maximum of t_{nonsup} and $-t_{noninf}$. This is equivalent to choosing the less significant result in the two-one-sided-test (TOST) procedure.

Non-estimable cases

When the model is rank-deficient, each row x of object's `linfct` slot is checked for estimability. If `sum(x*bhat)` is found to be non-estimable, then the string `NonEst` is displayed for the estimate, and associated statistics are set to NA. The estimability check is performed using the orthonormal basis N in the `nbasis` slot for the null space of the rows of the model matrix. Estimability fails when $\|Nx\|^2/\|x\|^2$ exceeds `tol`, which by default is $1e-8$. You may change it via `emm_options` by setting `estble.tol` to the desired value.

See the warning above that non-estimable cases are still included when determining the family size for P -value adjustments.

Warning about potential misuse of P values

Some in the statistical and scientific community argue that the term “statistical significance” should be completely abandoned, and that criteria such as “ $p < 0.05$ ” never be used to assess the importance of an effect. These practices can be too misleading and are prone to abuse. See the “basics” vignette for more discussion.

Note

In doing testing and a transformation and/or link is in force, any null and/or delta values specified must always be on the scale of the linear predictor, regardless of the setting for ‘type’. If `type = "response"`, the null value displayed in the summary table will be back-transformed from the value supplied by the user. But the displayed delta will not be changed, because there (often) is not a natural way to back-transform it.

When we have `type = "response"`, and `bias.adj = TRUE`, the null value displayed in the output is both back-transformed and bias-adjusted, leading to a rather non-intuitive-looking null value. However, since the tests themselves are performed on the link scale, this is the response value at which a *P* value of 1 would be obtained.

The default `show` method for `emmGrid` objects (with the exception of newly created reference grids) is `print(summary())`. Thus, with ordinary usage of `emmmeans` and such, it is unnecessary to call `summary` unless there is a need to specify other than its default options.

If a data frame is needed, `summary`, `confint`, and `test` serve this need. `as.data.frame` routes to `summary` by default; calling it with `destroy.annotations = TRUE` is not recommended for exactly that reason. If you want to see more digits in the output, use `print(summary(object), digits = ...)`; and if you *always* want to see more digits, use `emm_options(opt.digits = FALSE)`.

See Also[hpd.summary](#)**Examples**

```

warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)
warp.emm # implicitly runs 'summary'

confint(warp.emm, by = NULL, level = .90)

# -----
pigs.lm <- lm(log(conc) ~ source + factor(percent), data = pigs)
pigs.emm <- emmeans(pigs.lm, "percent", type = "response")
summary(pigs.emm) # (inherits type = "response")
summary(pigs.emm, calc = c(n = ".wgt.")) # Show sample size

# For which percents is EMM non-inferior to 35, based on a 10% threshold?
# Note the test is done on the log scale even though we have type = "response"
test(pigs.emm, null = log(35), delta = log(1.10), side = ">")

con <- contrast(pigs.emm, "consec")
test(con)

test(con, joint = TRUE)

# default Scheffe adjustment - rank = 3
summary(con, infer = c(TRUE, TRUE), adjust = "scheffe")

# Consider as some of many possible contrasts among the six cell means
summary(con, infer = c(TRUE, TRUE), adjust = "scheffe", scheffe.rank = 5)

# Show estimates to more digits
print(test(con), digits = 7)

# -----
# Cross-adjusting P values
prs <- pairs(warp.emm) # pairwise comparisons of tension, by wool
test(prs, adjust = "tukey", cross.adjust = "bonferroni")

# Same comparisons taken as one big family (more conservative)
test(prs, adjust = "bonferroni", by = NULL)

```

Description

This is a simulated unbalanced dataset with three factors and two numeric variables. There are true relationships among these variables. This dataset can be useful in testing or illustrating messy-data situations. There are no missing data, and there is at least one observation for every factor combination; however, the "cells" attribute makes it simple to construct subsets that have empty cells.

Usage

```
ubds
```

Format

A data frame with 100 observations, 5 variables, and a special "cells" attribute:

A Factor with levels 1, 2, and 3

B Factor with levels 1, 2, and 3

C Factor with levels 1, 2, and 3

x A numeric variable

y A numeric variable

In addition, `attr(ubds, "cells")` consists of a named list of length 27 with the row numbers for each combination of A, B, C. For example, `attr(ubds, "cells")[["213"]]` has the row numbers corresponding to levels `A == 2`, `B == 1`, `C == 3`. The entries are ordered by length, so the first entry is the cell with the lowest frequency.

Examples

```
# Omit the three lowest-frequency cells
low3 <- unlist(attr(ubds, "cells")[1:3])
messy.lm <- lm(y ~ (x + A + B + C)^3, data = ubds, subset = -low3)
```

untidy

Dare to be un-"tidy"!

Description

Users who use **emmeans** functions as part of a pipeline – or post-process those results in some other way – are likely missing some important information.

Details

Your best bet is to display the actual results without any post-processing. That's because **emmeans** and its relatives have their own `summary` and `print` methods that display annotations that may be helpful in explaining what you have. If you just pipe the results into the next step, those annotations are stripped away and you never see them. Statistical analysis is not just a workflow; it is a discipline that involves care in interpreting intermediate results, and thinking before moving on.

Examples

```
neur.glm <- glm(Pain ~ Treatment + Sex + Age, family = binomial(),
              data = neuralgia)

### The actual results with annotations (e.g. ests are on logit scale):
emmeans(neur.glm, "Treatment")

### Post-processed results lose the annotations
if(requireNamespace("tibble")) {
  emmeans(neur.glm, "Treatment") |> tibble::as_tibble()
}
```

update.emmGrid	<i>Update an emmGrid object</i>
----------------	---------------------------------

Description

Objects of class `emmGrid` contain several settings that affect such things as what arguments to pass to `summary.emmGrid`. The update method allows safer management of these settings than by direct modification of its slots.

Usage

```
## S3 method for class 'emmGrid'
update(object, ..., silent = FALSE)

## S3 replacement method for class 'emmGrid'
levels(x) <- value

## S3 method for class 'summary_emm'
update(object, by.vars, mesg, ...)
```

Arguments

<code>object</code>	An <code>emmGrid</code> object
<code>...</code>	Options to be set. These must match a list of known options (see Details)
<code>silent</code>	Logical value. If FALSE (the default), a message is displayed if any options are not matched. If TRUE, no messages are shown.
<code>x</code>	an <code>emmGrid</code> object
<code>value</code>	list or replacement levels. See the documentation for <code>update.emmGrid</code> with the <code>levels</code> argument, as well as the section below on “Replaciong levels”
<code>by.vars, mesg</code>	Attributes that can be altered in <code>update.summary_emm</code>

Value

an updated `emmGrid` object.

`levels<-` replaces the levels of the object in-place. See the section on replacing levels for details.

Details

The names in `...` are partially matched against those that are valid, and if a match is found, it adds or replaces the current setting. The valid names are

`tran`, `tran2` (list or character) specifies the transformation which, when inverted, determines the results displayed by `summary.emmGrid`, `predict.emmGrid`, or `emmip` when `type="response"`.

The value may be the name of a standard transformation from `make.link` or additional ones supported by name, such as `"log2"`; or, for a custom transformation, a list containing at least the functions `linkinv` (the inverse of the transformation) and `mu.eta` (the derivative thereof). The `make.tran` function returns such lists for a number of popular transformations. See the help page of `make.tran` for details as well as information on the additional named transformations that are supported. `tran2` is just like `tran` except it is a second transformation (i.e., a response transformation in a generalized linear model).

`tran.mult` Multiple for `tran`. For example, for the response transformation `'2*sqrt(y)'` (or `'sqrt(y) + sqrt(y + 1)'`, for that matter), we should have `tran = "sqrt"` and `tran.mult = 2`. If absent, a multiple of 1 is assumed.

`tran.offset` Additive constant before a transformation is applied. For example, a response transformation of `log(y + pi)` has `tran.offset = pi`. If no value is present, an offset of 0 is assumed.

`estName` (character) is the column label used for displaying predictions or EMMs.

`inv.lbl` (character)) is the column label to use for predictions or EMMs when `type="response"`.

`by.vars` (character) vector or NULL) the variables used for grouping in the summary, and also for defining subfamilies in a call to `contrast`.

`pri.vars` (character vector) are the names of the grid variables that are not in `by.vars`. Thus, the combinations of their levels are used as columns in each table produced by `summary.emmGrid`.

`alpha` (numeric) is the default significance level for tests, in `summary.emmGrid` as well as `plot.emmGrid` when `'CIs = TRUE'`. Be cautious that methods that depend on specifying `alpha` are prone to abuse. See the discussion in `vignette("basics", "emmeans")`.

`adjust` (character)) is the default for the `adjust` argument in `summary.emmGrid`.

`cross.adjust` (character)) is the default for the `cross.adjust` argument in `summary.emmGrid` (used for adjusting between groups).

`famSize` (integer) is the number of means involved in a family of inferences; used in Tukey adjustment

`infer` (logical vector of length 2) is the default value of `infer` in `summary.emmGrid`.

`level` (numeric) is the default confidence level, `level`, in `summary.emmGrid`. *Note:* You must specify all five letters of 'level' to distinguish it from the slot name 'levels'.

`df` (numeric) overrides the default degrees of freedom with a specified single value.

`calc` (list) additional calculated columns. See `summary.emmGrid`.

`null` (numeric) null hypothesis for summary or test (taken to be zero if missing).

- side (numeric or character) side specification for for summary or test (taken to be zero if missing).
- sigma (numeric) Error SD to use in predictions and for bias-adjusted back-transformations
- delta (numeric) delta specification for summary or test (taken to be zero if missing).
- predict.type **or** type (character) sets the default method of displaying predictions in `summary.emmGrid`, `predict.emmGrid`, and `emmip`. Valid values are "link" (with synonyms "lp" and "linear"), or "response".
- bias.adjust, frequentist (logical) These are used by summary if the value of these arguments are not specified.
- estType (character) is used internally to determine what adjust methods are appropriate. It should match one of 'c("prediction", "contrast", "pairs")'. As an example of why this is needed, the Tukey adjustment should only be used for pairwise comparisons (estType = "pairs"); if estType is some other string, Tukey adjustments are not allowed.
- avgd.over (character) vector) are the names of the variables whose levels are averaged over in obtaining marginal averages of predictions, i.e., estimated marginal means. Changing this might produce a misleading printout, but setting it to `character(0)` will suppress the "averaged over" message in the summary.
- initMesg (character) is a string that is added to the beginning of any annotations that appear below the `summary.emmGrid` display.
- methDesc (character) is a string that may be used for creating names for a list of `emmGrid` objects.
- nesting (Character or named list) specifies the nesting structure. See "Recovering or overriding model information" in the documentation for `ref_grid`. The current nesting structure is displayed by `str.emmGrid`.
- levels named list of new levels for the elements of the current `emmGrid`. The list name(s) are used as new variable names, and if needed, the list is expanded using `expand.grid`. These results replace current variable names and levels. This specification changes the levels, grid, roles, and misc slots in the updated `emmGrid`, and resets `pri.vars`, `by.vars`, `adjust`, `famSize`, and `avgd.over`. In addition, if there is nesting of factors, that may be altered; a warning is issued if it involves something other than mere name changes. *Note:* All six letters of `levels` is needed in order to distinguish it from `level`.
- submodel formula or character value specifying a submodel (requires this feature being supported by underlying methods for the model class). When specified, the `linfct` slot is replaced by its aliases for the specified sub-model. Any factors in the sub-model that do not appear in the model matrix are ignored, as are any interactions that are not in the main model, and any factors associate with multivariate responses. The estimates displayed are then computed as if the sub-model had been fitted. (However, the standard errors will be based on the error variance(s) of the full model.) *Note:* The formula should refer only to predictor names, *excluding* any function calls (such as `factor` or `poly`) that appear in the original model formula. See the example.
- The character values allowed should partially match "minimal" or "type2". With "minimal", the sub-model is taken to be the one only involving the surviving factors in object (the ones averaged over being omitted). Specifying "type2" is the same as "minimal" except only the highest-order term in the submodel is retained, and all effects not containing it are orthogonalized-out. Thus, in a purely linear situation such as an `lm` model, the joint test of the modified object is in essence a type-2 test as in `car::Anova`.

Please note that it is possible (or even likely) that there will be disparity between the `grid` and `linfct` slots when a submodel is used. This is because `grid` contains the *claimed* values of the predictors and `linfct` contains *aliases* of them computed from the submodel.

For some objects such as generalized linear models, specifying `submodel` will typically not produce the same estimates or type-2 tests as would be obtained by actually fitting a separate model with those specifications. The reason is that those models are fitted by iterative-reweighting methods, whereas the `submodel` calculations preserve the final weights used in fitting the full model.

(any other slot name) If the name matches an element of `slotNames(object)` other than `levels`, that slot is replaced by the supplied value, if it is of the required class (otherwise an error occurs).

The user must be very careful in replacing slots because they are interrelated; for example, the lengths and dimensions of `grid`, `linfct`, `bhat`, and `V` must conform.

Replacing levels

The `levels<-` method uses `update.emmGrid` to replace the levels of one or more factors. This method allows selectively replacing the levels of just one factor (via subsetting operators), whereas `update(x, levels = list(...))` requires a list of *all* factors and their levels. If any factors are to be renamed, we must replace all levels and include the new names in the replacements. See the examples.

Method for `summary_emm` objects

This method exists so that we can change the way a summary is displayed, by changing the by variables or the annotations.

Note

When it makes sense, an option set by `update` will persist into future results based on that object. But some options are disabled as well. For example, a `calc` option will be nulled-out if `contrast` is called, because it probably will not make sense to do the same calculations on the contrast results, and in fact the variable(s) needed may not even still exist. `factor(percent)`.

See Also

[emm_options](#)

Examples

```
# Using an already-transformed response:
pigs.lm <- lm(log(conc) ~ source * factor(percent), data = pigs)

# Reference grid that knows about the transformation
# and asks to include the sample size in any summaries:
pigs.rg <- update(ref_grid(pigs.lm), tran = "log",
                 predict.type = "response",
                 calc = c(n = ~.wtg.))
emmmeans(pigs.rg, "source")
```

```

# Obtain estimates for the additive model
# [Note that the submodel refers to 'percent', not 'factor(percent)']
emmmeans(pigs.rg, "source", submodel = ~ source + percent)

# Type II ANOVA
joint_tests(pigs.rg, submodel = "type2")

## Changing levels of one factor
newrg <- pigs.rg
levels(newrg)$source <- 1:3
newrg

## Unraveling a previously standardized covariate
zd = scale(fiber$diameter)
fibz.lm <- lm(strength ~ machine * zd, data = fiber)
(fibz.rg <- ref_grid(fibz.lm, at = list(zd = -2:2))) ### 2*SD range
lev <- levels(fibz.rg)
levels(fibz.rg) <- list (
  machine = lev$machine,
  diameter = with(attributes(zd),
    `scaled:center` + `scaled:scale` * lev$zd )
)
fibz.rg

### Compactify results with a by variable
update(joint_tests(pigs.rg, by = "source"), by = NULL)

```

xtable.emmGrid

Using xtable for EMMs

Description

These methods provide support for the **xtable** package, enabling polished presentations of tabular output from [emmmeans](#) and other functions.

Usage

```

## S3 method for class 'emmGrid'
xtable(x, caption = NULL, label = NULL, align = NULL,
  digits = 4, display = NULL, auto = FALSE, ...)

## S3 method for class 'summary_emm'
xtable(x, caption = NULL, label = NULL,
  align = NULL, digits = 4, display = NULL, auto = FALSE, ...)

## S3 method for class 'xtable_emm'
print(x, type = getOption("xtable.type", "latex"),
  include.rownames = FALSE, sanitize.message.function = footnotesize, ...)

```

Arguments

x	Object of class emmGrid
caption	Passed to <code>xtableList</code>
label	Passed to <code>xtableList</code>
align	Passed to <code>xtableList</code>
digits	Passed to <code>xtableList</code>
display	Passed to <code>xtableList</code>
auto	Passed to <code>xtableList</code>
...	Arguments passed to <code>summary.emmGrid</code>
type	Passed to <code>print.xtable</code>
include.rownames	Passed to <code>print.xtable</code>
sanitize.message.function	Passed to <code>print.xtable</code>

Details

The methods actually use `xtableList`, because of its ability to display messages such as those for P-value adjustments. These methods return an object of class "xtable_emm" – an extension of "xtableList". Unlike other xtable methods, the number of digits defaults to 4; and degrees of freedom and *t* ratios are always formatted independently of digits. The print method uses `print.xtableList`, and any ... arguments are passed there.

Value

The xtable methods return an xtable_emm object, for which its print method is `print.xtable_emm`.

Examples

```
if(requireNamespace("xtable"))
  emm_example("xtable")
  # Use emm_example("xtable", list = TRUE) # to just list the code
```
